## Abstract

The Nicholas reaction is the reaction of a cobalt-stabilised propargyl cation with a nucleophile and the aim of this project was to attempt this reaction with a chiral substrate in an effort to effect an asymmetric Nicholas reaction. A range of contemporary techniques were applied to reach this goal.

Initially an attempt was made to reproduce an earlier successful racemic synthesis of a fused carbocyclic compound using a chiral precursor. It was envisaged that this would be approached using a 1,4-conjugate addition to an enone using a chiral ligand to install the C-3 alkenyl group selectively. Although the conjugate addition reactions were successful, using well tried and tested ligands, the enantiomeric excesses were very low and unfortunately a suitable chelating catalyst that prevent fulfil the requirements was not identified at this stage of the investigation.

The next approach made use of an asymmetric alkynylation reaction to an aldehyde. This was successfully carried out using a Carreira asymmetric alkynylation reaction to afford optically active propargyl alcohols with good to excellent enantiomeric excess ( $50 \%-82 \%$ ees). The desired optical active propargyl alcohols were then complexed, with dicobalt octacarbonyl, to afford the corresponding dicobalt hexacarbonyl complexes. These then successfully underwent the corresponding Nicholas cyclisation reaction to afford, after oxidative decomplexation of the cobalt species, a range of optically active chromane and isochromanes with ees of ( $45 \%-81 \%$ ). In a second study a series of optically active benzopyran derivatives were also successfully synthesised, using the same methodology, again with high levels of enantiomeric excess ( $87 \%$ -94\%)

In the final phase of this investigations it was explored the use of chiral derivatives of the chiral pool molecule citronellal as well as an achiral analogue in an effort to afford novel chiral aldehydes for propargylation and cyclisation. The new chiral centres were successfully installed using chiral auxiliary technology however unexpectedly difficulties were encountered in the removal of the chiral auxiliary. A lack of time, in order to further explore the removal step, unfortunately meant that this was put on hold for further studies.

## Acknowledgements

My first debt of gratitude must go to my husband, Alireza, who a lot to make my way smooth to do my phd. Alireza made all energy and power to start, continue and complete this phd with his love and encouragement. He already has my heart so I will just give him a heartfelt "thanks".

Special thanks to special scientist, my director of study, Professor Elizabeth Tyrrell. Without of her support this work would not get to end. She is a patiently provided the vision, encouragement and advices necessary for me to proceed through the PhD program. I learn alot from her in chemistry and morality. I also want to thank my second supervisor Dr. Donatella Banti for her supportive adviser to me throughout my phd.

I would like to thank all the technical staff at Kingston University especially Dr. JeanMarie Peron for his unexceptional help with NMR expriments and Dr. Julian Swindan for teaching me how to use the hplc. I would like to thank Dr. Siamak Soltati for his help in mass spectroscopy and aslo all of his family to making good times in the UK.

I am grateful to the EPSRC National Mass Spectroscopy Service Centre, at Swansea University for running all my high-resolution mass spectroscopy.

I am taking this opportunity to thank my sponsor Azad University of Omidie for funding this project and Azad University, Oxford for their support and also friends in Iran, without their support this work did not start and not complete, Dr Masoud Sarhadi, Dr. Asad Joata Bayrami and Dr. Zohreh Saadati and also my lovely friend Farkhondeh Barzideh.

I am very thankful to all of my friends in EM213 especially Dr. Elena Polycarpou for her invaluable help in all respect also Dr. Hadi Bordbar and his wife (Helen), Dr. Ammara Abdullah, Salah E Breidi, Syeda A Shah.

I wish to thank my parents, Ziba Safaei and Hamid Mazloumi. Their love provided my inspiration and was my driving force. I owe them everything and wish I could show them just how much I love and appreciate them. My sister, Khatereh and my brothers Alireza and Iman. I also want to thank to my in-laws for their unconditional support. Finally, I would like to dedicate this work to my lost relative, Esmaeel, who left us too soon. I hope that this work makes you proud.

## 1 Introduction

### 1.1 Aims of the Project

The main aim of this study has been an investigation into an asymmetric Nicholas reaction. During the course of this study it was explored a number of different strategies in order to achieve this aim. These include:

- the use of a chiral catalyst (discussed in sections 2.4.1)
- the use of a chiral pool (section 2.7)
- the use of a chiral auxiliary (section 2.8).
- The final and most successful approach involved the participation of a chiral propargyl alcohol in a series of asymmetric Nicholas cyclisation reactions (sections 2.5, 2.6).

This chapter has been organised such that each of the key methodologies that were investigated in this project such as methods for asymmetric synthesis, conjugate addition strategies and the key Nicholas reaction itself are presented. Further detailed descriptions will then be forthcoming, where appropriate, in the results and discussion section.

### 1.2 Stereochemistry and Chirality

Stereochemistry attempts to define the three dimensional configuration of a molecule. ${ }^{1,2}$ The arrangement of the groups around an $\mathrm{sp}^{3}$ hybridised carbon atom that is bonded to four different groups may result in one of two arrangements (Figure 1.1). ${ }^{3}$ Although the four groups around 1 and 2 are the same, the two compounds are not identical. Compounds 1 and 2 are nonsuperimposable mirror images of each other and they are termed enantiomers (Figure 1.1). Molecules that demonstrate this property are called chiral molecules and the atom that the groups are bonded to is called the chiral centre. For compounds 1 and 2 the chiral centre is a carbon atom however, this is not a prerequisite for chirality. ${ }^{2 b}$

1

2

Figure 1.1: Non-superimposable mirror image compound 1 and 2

Enantiomers are an example of stereoisomerism and for a chiral compound with an $n$ chiral centre; the maximum number of possible stereoisomers are $2^{n}$. If $n=1$. In the case of compounds 3-6, the number of stereoisomers is 2 (hence 2 enantiomers). ${ }^{2 a}$ When $n=2$ four stereoisomers such as compounds 3-6 are possible (Figure 1.2).

3

5

4

6

Figure 1.2: Four stereoisomers for a compound with 2 chiral centres

Compounds 3 and 4 are non-superimposable mirror-images of each other and as such they are enantiomers (as are compounds 5 and 6). Compounds 3 and 6 or 5 and 4 are not mirror-images and are referred to as diastereoisomers. ${ }^{2 b}$ By convention, chiral centres are identified with either $R$ (for rectus) or as $S$ (for sinister). The $R$ - or $S$-chiral centres are designated according to the Cahn-Ingold-Prelog (CIP) priority rules. ${ }^{4}$ The substituents, about the chiral centre, are each assigned a priority based upon the corresponding atomic number. Consider compound 7 (Figure 1.3) in which the four functional groups have been prioritised according to the CIP rules thus $\mathrm{Br}>\mathrm{Et}>\mathrm{Me}>\mathrm{H}$. Viewing the groups in descending priority $\mathrm{Br}, \mathrm{Et}$, Me occurs in an anti-clockwise direction hence the absolute configuration is designated as $(S)$. The enantiomer to 7 will therefore be assigned an (S)-configuration. ${ }^{4}$

Figure 1.3: A compound with (S)-Configuration

Enantiomers have the same physicochemical properties. An important feature of enantiomers is their interaction with the plane of plane polarised light. This is measured using an instrument called a polarimeter (Figure 1.4). ${ }^{5}$

Figure 1.4: The principles of a polarimeter ${ }^{6}$

The polarizer filter provides light which oscillates in one plane and as this plane polarised light interacts with the optically pure compound in the sample tube the plane of the plane polarised light is rotated. The degree of rotation is called the angle of rotation $(\alpha)$, and can be rotated either clockwise or anticlockwise depending on the enantiomer. This is converted to a positive or negative integer on a digital screen. In the diagram above, the angle of rotation ( $\alpha$ ), as observed by the viewer has been rotated clockwise by about $80^{\circ}$. If an equimolar mixture of $(R)$ and (S)-enantiomers (a racemic mixture) are placed in a polarimeter tube the angle of rotation measured will be zero as each enantiomer will interact with the plane of plane polarised light in an equal amount and will rotate it in opposite directions.

The optical activity of chiral molecules are usually designated as either (+) or (-) depending upon whether the plane polarised light is rotated clockwise, (+), or anticlockwise (-). Optically pure (S)-(-)-2-methyl-1-butanol 8 has a specific rotation $[\alpha]_{\mathrm{D}}=-5.8^{\circ}$. The prefix $(S)$-describes the absolute configuration about the chiral centre, the $(-)$ indicates that this compound rotates the plane of plane
polarised light in an anticlockwise direction. Compound 8 (Figure 1.5) has a specific rotation of $[\alpha]=-5.8^{\circ} .{ }^{5}$ The specific rotation of a chiral compound is the observed angle of optical rotation ( $\alpha$ ) divided by the length of the cell $(I)$ and the concentration of the solution (c) ${ }^{7}$ and is characteristic of a compound $\left([\alpha]=\frac{\alpha}{1 . c}\right)$.

8
Figure 1.5: (S)-(-)-2-Methyl-1-butanol

A synthetic procedure that results in the formation of a single enantiomer is called an asymmetric synthesis. ${ }^{8}$ In the field of chemistry forming one stereoisomer is an important challenge because in an achiral environment, i.e. experimental reaction conditions that are devoid of any chiral control, equimolar quantities of enantiomers, (ie a racemic mixture) will result when a chiral centre is formed. Consider the nucleophilic addition to ketone 9 (Scheme 1.1). ${ }^{8}$

Scheme 1.1: Formation of racemic alcohols

In the absence of an asymmetric environment there is an equal probability that the incoming nucleophile $\left(\mathrm{Nu}^{-}\right)$may add from either side of the planar carbonyl in 9 resulting in an equimolar mixture of both enantiomers 10 and $11 .{ }^{9}$ Such a 50:50 mixture of enantiomers is called a racemic mixture and results from the fact that the transition state to either 10 or 11 are enantiomeric and hence identical in energy (Figure 1.6).
According to the IUPAC defenistion enantiomeric excess is the absolute difference between the mole fractions of each enantiomer which expressed as a percent enantiomer excess. To determine enantiomeric excess percentage, if the amount of each enantiomer is available, enantiomer excess can be determined by: $\frac{\text { major enantiomer - minor enantiomer }}{\text { major enantiomer }+ \text { minor enantioer }} \times 100$, if specific rotation and observed rotations are available can be determined by: $\frac{\text { observed rotation }(\alpha)}{\text { specific rotation }[\alpha]} \times 100$.

Figure 1.6: Enantiomeric transition state

### 1.2.1 The Importance of Stereochemistry

To an organic chemist asymmetric synthesis is a process that selectively produces one or more new elements of chirality ${ }^{1,10}$ This is important in the field of pharmaceuticals and natural products as the physiological effects of enantiomers are often different (Figure 1.7). ${ }^{11}$ For example, ( $R$ )-(-)-propranolol 12 was introduced in the 1960s for use as a $\beta$-blocker for the treatment of heart disease. The (S)-(+) enantiomer 13, in contrast, is used as a contraceptive. ${ }^{12}$

12

13

Figure 1.7: Enantiomers of propranolol
A possible explanation for this phenomenon is shown below in (Figure 1.8). It attempts to portray how an optically active compound might interact with a binding site. The active enantiomer (Figure 1.8A) has the correct 3-point interaction with the drug binding site in order to elicit the correct physiological response such as dilate the pupil, contract a muscle or release a hormone. In contrast, the enantiomer (Figure 1.8B) is only able to make a two-point interaction as there is a mismatch between the "blue ligand" and the corresponding "green binding site" on the receptor. As a result of this the
enantiomer is predicted to be either totally inactive or elicit an alternative and possibly detrimental response. ${ }^{11}$

Figure 1.8: Interaction of receptors and drugs ${ }^{11}$
Chiral drug molecules, therefore, interact with receptors and enzymes and elicit a response because they are chiral and possess the correct shape and size to interact with the binding/active site. ${ }^{12}$ These effects are also evident in senses such as the sense of smell for instance. The two enantiomers of carvone which are (R)-(-)-carvone 14, the principal component of spearmint oil and (S)-(+)carvone 15, the principal component of caraway seed oil (Figure 1.9). The two enantiomers do not smell the same with each enantiomer having its own characteristic odour. ${ }^{13}$ The effect is subjective as the spearmint smell of $\mathbf{1 4}$ is not always detected by all. However most people do detect a difference in their smells. Again this difference is explained in terms of their different behaviour towards receptor sites in the nose. These volatile molecules occupy only those odour receptors that have the complimentary shape to accommodate them. Because the receptor binding sites are themselves chiral, one enantiomer fits one kind of receptor while the other enantiomer fits a different kind. ${ }^{14}$

14

15

Figure 1.9: Enantiomers of Carvone

Over $80 \%$ of small drugs approved by food and drug administration (FDA) are small chiral molecules for clinical applications of which 75 \% exist as single enantiomers. ${ }^{15}$ Considering the different effects that optical isomers can have on biological systems, it is very important to ensure an efficient asymmetric synthesis in order to prepare single enantiomeric drugs. A single optical isomeric compound that is of relevance to this project is cromakalim 16 a KATP - dependant potassium channel activator (Figure 1.10).

16
Figure 1.10: Structure of cromakalim 16

Potassium channels are membrane proteins that selectively conduct potassium ions across the cell membrane. Among the various types of potassium channels are the adenosine triphosphate (ATP) sensitive potassium channel (K $\mathrm{A}_{\text {ATP }}$ channels) which are regulated by changes in the intracellular [ATP]/[ADP] ratio. ${ }^{16}$ Compounds, such as cromakalim 16, open Katp - channels and have thus been named "potassium channel openers" (PCOs). ${ }^{17,18}$ The net effect of their action is the reduction of high blood pressure. ${ }^{19}$ However, cromakalim 16, lacks specificity resulting in undesirable side effects. ${ }^{20}$ New vasorelaxant analogues of this benchmark drug that retain the potency of cromakalim 16 but lack the toxicity, have been explored in recent years. ${ }^{21}$ Tyrrell et al ${ }^{22 a,}{ }^{22 i}$ have reported novel benzopyran derivatives that were obtained via an intramolecular Nicholas reaction, with antihypertensive activity. The Nicholas reaction will be discussed below.

### 1.3 The Nicholas reaction

The Nicholas reaction is the reaction of a propargyl cation stabilized as the corresponding dicobalt hexacarbonyl complex, with a nucleophile ${ }^{23}$ (Scheme 1.2).

Scheme 1.2: The Nicholas reaction

Initially the propargyl alcohol/ether 17 is protected, by reaction with dicobalt octacarbonyl, to afford the corresponding hexacarbonyl complex 18. Upon exposure to a protic /Lewis acid, a dicobalt hexacarbonyl stabilised propargylic cation 19 is formed. Subsequent reaction of the cation 19 with a nucleophile affords the complexed product 20 in which the -OR moiety has been substituted by a nucleophile ( Nu ). Oxidative decomplexation of complex 20 affords the Nicholas adduct 21. The Nicholas reaction thus enables the efficient substitution reaction of propargyl alcohols/ethers. ${ }^{24}$

### 1.3.1 Role of the complex

Clearly the role of cobalt is essential to the reliability of the Nicholas reaction. Cobalt is a transition metal element with electron configuration [Ar] $4 \mathrm{~s}^{2} 3 \mathrm{~d}^{7}$. In its pure form, it is a steel-grey to black shiny hard metal. It also exists as cobalt (II) and cobalt (III), which can form a number of organic and inorganic salts. ${ }^{25}$ Two structures, 22a and 22b are thought to exist in solution the dicobalt octacarbonyl complex and to be rapidly interconverted (Figure 1.11) In each structure dicobalt octacarbonyl complex is a stable complex as each cobalt atom has eighteen electrons in the outer shell and therefore follows the 18 -valence electron rule (Table 1.1). ${ }^{26,27}$

22a
22b

Figure 1.11: The structures for dicobalt octacarbonyl

Table 1.1: The Eighteen Electron Rule of the Dicobaltoctacarbonyl

| isomers | 22a | 22a |
| :---: | :---: | :---: |
| Cobalt | 9 valence electrons | 9 valence electrons |
|  |  |  |
| CO groups | $2 \times 4$ terminal $\mathrm{CO}=8$ |  |
| electrons | (2 Bridged $\mathrm{CO}+2 \times 3$ terminal |  |
|  |  | $\mathrm{CO})=$ |
|  |  | $2+6=8$ electrons |

Evidence for these structural types have been obtained from various spectroscopic analyses. The bridging carbonyl 22b has a $v(C O)$ stretch in the infra-red (IR) spectrum at about $1800 \mathrm{~cm}^{-1}$ this is much lower than that of terminal carbonyls and more analogous to an organic ketone $\mathrm{R}_{2} \mathrm{C}=\mathrm{O}$ which has a $v(\mathrm{CO})$ stretch at $1750 \mathrm{~cm}^{-1}$. In solution $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ has a structure with only terminal carbonyl moieties, i.e. four carbonyl groups per cobalt atom as suggested by structure 22a. The terminal $v(C O)$ stretch occurs at about $1950-2000 \mathrm{~cm}^{-1}$. 28,29 By complexing the alkyne functional group in compound 17 with dicobalt hexacarbonyl, there is both an increased stability and ease of formation of the propargylic cation 19. The principal role of the cobalt complex, however, is one of protecting the alkyne by avoiding the formation of a competing allene such as 23. Indeed allene formation is frequently an unwanted side reaction that occurs in the absence of dicobalt hexacarbonyl complexation however this is completely prevented by co-ordination with dicobalt hexacarbonyl (Scheme 1.3).

Scheme 1.3: Allene formation

The stabilisation by the complex may be rationalised when one considers the accepted structure of complexes such as 19. The use of the arrow, or the vertical line, that projects from the triple bond to the cobalt complex is the accepted "shorthand" depiction of the cobalt complex however in reality the structure of the complex is more like that shown in structure 24 (Figure 1.12).

19

24

Figure 1.12: Structure of cobalt complexed cation 24

The role of the cobalt atom, in the dicobalt hexacarbonyl complex, was initially elucidated by Seyferth ${ }^{30}$ in 1970 who suggested that the additional stabilisation of the cation resulted from the delocalisation of the positive charge from the propargylic position in $\mathbf{2 5}$ onto the two corresponding cobalt moieties as shown in structures 26 and 27 (Figure 1.3). ${ }^{30}$

Figure 1.13: Stability of dicobalt hexacarbonyl cation 25 using the Seyferth model

There is spectroscopic evidence ${ }^{31}$ in support of this suggestion. It has been observed that, upon complexation with dicobalt octacarbonyl, the sp-hybridised
$C \equiv C$ alkyne bond assumes more $\mathrm{sp}^{2}$ bond characteristics and this may be readily observed by both IR and NMR spectroscopy. In the IR spectrum of a propargyl alcohol, the $\mathrm{C} \equiv \mathrm{C}$ bond is readily observed at $2975 \mathrm{~cm}^{-1}$ however this absorbance is significantly reduced or absent in the corresponding dicobalt hexacarbonyl complex. In the ${ }^{1} \mathrm{H}$ NMR of a terminal uncomplexed alkyne the $\mathrm{C}=\mathrm{CH}$ proton resonates at about $\delta 3.00 \mathrm{ppm}$ however in the corresponding complex this resonance is shifted downfield to about $\delta 6.00 \mathrm{ppm}$. Schreiber has also offered an analogous model for the stability of the cobalt complexed cation. ${ }^{32,33}$

### 13.2 Dynamic behaviour of hexacarbonyl dicobalt

Dicobalt hexacarbonyl complexed propargylic cations are stabilised by the presence of the metal species. Hoffman ${ }^{34}$ suggested that additional stabilisation of the dicobalt hexacarbonyl cation is experienced when the cationic carbon atom is bent toward one of the cobalt atoms, shown in structure 28b and 28c, compared to the perpendicular structure 28a. The calculated energy for the perpendicular structure 28 a is about $17.5 \mathrm{kcal} / \mathrm{mol}$ higher than $\mathbf{2 8 b}$ and $\mathbf{2 8 c}$ and is attributed to hyperconjugation (Figure 1.14). ${ }^{31 \mathrm{~b}}$

28a

28b

28c

Figure 1.14: Hoffman's additional stability of tricobalt nonacarbonyl cation

Mislow and Norton ${ }^{27 a, 35}$ provided further experimental evidence for the bent structure of dicobalt hexacarbonyl stabilised cations via the use of ${ }^{13} \mathrm{C}$ NMR experiments (Figure 1.15). Low temperature $\left(-52^{\circ} \mathrm{C}\right)$ NMR studies showed that for the proposed complexes 29a and 29b, two distinct doublets were observed for the isopropyl $\left(\mathrm{CH}_{3}\right)$ substituents. The bent structures for 29a and 29b are suggested by the evidence of the two methyl groups being seen, on the NMR timescale as diastereotopic.

Figure 1.15: Evidence of the proposed bent structure of dicobalt hexacarbonyl cation

Schreiber ${ }^{25}$ proposed two mechanisms for the apparent interconversion of the diastereotopic methyl groups such as these, either:

1. carbon-carbon bond rotation around the double bond
2. simultaneous rotation and migration of the alkylidene ligand from one cobalt tricarbonyl unit to the other (Figure 1.15). Hoffman ${ }^{34}$ calculated that this process should involve a lower energy pathway.

The second process led to the use of the term the "fluxional nature" of the cobalt cation to describe the additional stabilisation obtained. Schreiber went on to provide an explanation for this phenomenon using transition state and orbital symmetry models. ${ }^{23}$

Nicholas also used NMR studies to show the temperature dependant behaviour of cobalts complexes such as 30 . Whereas ${ }^{13} \mathrm{C}$ NMR spectroscopy at $0{ }^{\circ} \mathrm{C}$ showed one methyl signal for the 2 vinyl methyl groups, the corresponding lower temperature study, at $-40^{\circ} \mathrm{C}$, clearly showed two signals for cation $30 .{ }^{31 \mathrm{~b}}$ An energy barrier of $11.5 \mathrm{kcal} / \mathrm{mol}$ was calculated on the basis of these observations. ${ }^{36}$

30
Figure 1.16: The proposed bent structure of dicobalt hexacarbonyl cation 30

The existence of two methyl signals at the low temperature is not consistent with a symmetrical structure and is suggestive of considerable charge delocalization onto the cobalt tricarbonyl unit (Figure 1.16). ${ }^{36}$

The first X-ray crystal structure of a hexacarbonyl dicobalt complexed propargyl cation was published by Melikyan ${ }^{27 a}$ in 1998. This was obtained from the stabilised cation 32 and helped to confirm the role played by the two $\mathrm{Co}_{2}(\mathrm{CO})_{6}$ groups in providing enhanced stability as well as greater crystallinity of the cation (Scheme 1.4).

31

32

Scheme 1.4: Melikyan's cation 32

The crystal structure of 31 was compared to the structure of the corresponding $\mathrm{sp}^{2}$ hybridised cation 32. In general, the orbitals of the covalent bonds around the central carbon atom in 32 are shorter than normal. The dicobalt hexacarbonyl complexes in 31 are essentially equal with the $\mathrm{C} \equiv \mathrm{C}$ and Co-Co bonds lying perpendicular to each other with angles very close to $90^{\circ}$. However in 32 the metal complexes are non-equivalent with one adopting a twist of $7.7^{\circ}$ away from
perpendicular. The central carbon atom becomes shifted towards one of the cobalt atoms in each Co-Co pair whereas in 31 they are equidistant.

### 1.3.3 Decomplexation of the hexacarbonyl dicobalt complex

The oxidative decomplexation of the dicobalt hexacarbonyl complex is now widely established in the literature. ${ }^{24,37}$ Some of the oxidative and reductant methods include:

1. Ferric nitrate ${ }^{38}$
2. Ceric ammonium nitrate $(\mathrm{CAN})\left[\left(\mathrm{NH}_{4}\right)_{2} \mathrm{Ce}\left(\mathrm{NO}_{3}\right)_{6}\right]^{39}$
3. Trimethylamine $N$-oxide ${ }^{22 d, 40}$ or $N$-morpholine $N$-oxide, often in conjuction with 1,4-cyclohexandiene ${ }^{41}$
4. Tetrabutylammonium fluoride ${ }^{40}$
5. Sodium methanethiolate ${ }^{24}$
6. Pyridine ${ }^{24}$
7. Dimethylsulfoxide/water ${ }^{24}$

A comparison of methods for cobalt decomplexation of 33 is shown in Table 1.2. From this study it is clear that $N$-morpholine $N$-oxide provided the better yield. 24,40,42

33
Scheme 1.5: Decomplexation reaction
Table 1.2: Oxidative Decomplexation Reaction Conditions
$\left.\begin{array}{|c|c|c|}\hline R & \text { Conditions } & \text { Yield } \\ \hline \mathrm{Me} & \begin{array}{c}\text { CAN, NEt } \\ 3\end{array} \\ \mathrm{THF} / \text { acetone } 0{ }^{\circ} \mathrm{C}\end{array}\right] .72$

### 1.3.4 Stereoselective Nicholas reactions

Several general reviews on the Nicholas reaction have been disseminated in the past decade ${ }^{24}$ however in this section the focus will be on stereoselectivity in the Nicholas reaction.

### 1.3.4.1 Stereoselective intermolecular Nicholas reactions

The syn diastereoselective aldol products 36a-b were generated by treating the complexed alkynyl acetal 35 with prochiral enolsilane 34 at $-78^{\circ} \mathrm{C}$. Standard cobalt decomplexation conditions with CAN were used. ${ }^{37}$

Scheme 1.6: Stereoselective intermolecular Nicholas reaction

It has been suggested by the author that both 36a and 36b are derived from a less crowded anticlinal transition state 37 b . They differ only in the degree of crowding between the complex and the ring in 38a and the complex and the OTMS group in 38b. It is clear from the distribution of diastereoisomers, that favour 38a, that the repulsion is minimal in this transition state (Figure 1.17). ${ }^{37}$

37a (synclinal)

38a (syn)

38b (anti)

Figure 1.17: Syn and anti-diastereomeric transition states

The Schreiber group synthesised the ketones 41 a and 41 b with high levels of (syn:anti, 18:1) diastereoselectivity via a reaction between the $O$ - silylenol ether 39 and the dicobalt hexacarbonyl complexed propargyl ether 40 in the presence of the Lewis acid $\mathrm{EtAlCl}_{2}\left(\right.$ Scheme 1.7). ${ }^{40-41}$

39
40

41b

Scheme 1.7: Synthesis of the diastereoselective ketone

Shuto ${ }^{43}$ and co-workers reported a diastereoselective Nicholas reaction by using an azide, as a nucleophile, with the amide 42. The propargylic chiral centre which is $-(R)$ in the substrate 42 was converted to an $-(S)$ in the product 43 via the proposed transition state 44 (Scheme 1.8). This outcome serves to confirm that despite the stabilised cation 44 being planar the configuration of the substrate 42 is "remembered" and the nucleophile attacks anti to the leaving group to provide product 43 in a consistently diastereoselective way consistent with Schreiber's hypothesis.

Scheme 1.8: A diastereoselective Nicholas reaction of the amide 42

Following on from the study by Schreiber ${ }^{40-41}$ Tyrrell was also able to demonstrate a similar syn diastereoselective intermolecular Nicholas reaction between the O-silylenol ether 46 and the dicobalt hexacarbonyl stabilised propargylic cation, derived from diol 45, to obtain propargylic alcohol 47. (Scheme 1.9) ${ }^{44}$

Scheme 1.9: A syn diastereoselective intermolecular Nicholas reaction

### 1.3.4.2 Stereoselective intramolecular Nicholas reactions

An intramolecular reaction involves only one molecule that contains both the nucleophile and the electrophile. The reaction is faster because the nucleophile and electrophile are held close together and results in the formation of a ring. ${ }^{45}$
Grove $^{46}$ reported the generation of a cis-tricycle 49, using an intramolecular ring closure in their intramolecular Nicholas reaction. In this particular example the
aromatic ring, contained in the precursor 48, served as the nucleophile in a Friedel Crafts type reaction and represent one of the first examples of its type used in Nicholas chemistry (Scheme 1:10).

Scheme 1.10: An intramolecular Nicholas reaction

Martinn and Palazón ${ }^{47}$ reported an intramolecular Nicholas reaction of the linear diol 50. Treatment of the complex with boron trifluoride dietherate at $-30^{\circ} \mathrm{C}$ gave the corresponding monocyclic ethers 51 trans and 52 cis in good yield with a 3:1 trans:cis diastereoselectivity (Scheme 1.11).

Scheme 1.11: An intramolecular Nicholas reaction
Schreiber ${ }^{40}$ reported the synthesis of the exocyclic enyne 55 from the allylic silane 53. This underwent an intramolecular Nicholas reaction with complete trans stereo control to afford, after decomplexation, the alkyne 55 in $89 \%$ yield (Scheme 1.12). ${ }^{40}$

53

54

55

Scheme 1.12: Synthesis of the exocyclic enyne

Tyrrell reported ${ }^{48}$ a similar trans selectivity in the synthesis of the carbocycle 57 via an intramolecular Nicholas reaction of 56, this resulted in the exo-cyclic keto compound 57 with trans stereoselectivity from hexacarbonyl O-silylether dicobalt 56 (Scheme 1.13).

56
57
Scheme 1.13: Synthesis of exocyclic enyne

In 1997, Tyrrell ${ }^{22 a}$ used an intramolecular Nicholas Reaction in the cyclisation reaction to synthesise derivatives of the benzopyran 59 from propargyl alcohol 58. The various precursors analogous to 58 were synthesised from salicylaldehyde derivatives. NMR studies of 59 were used to elucidate the cisconfiguration of the key cyclisation reaction (Scheme 1.14).

Scheme 1.14: Synthesis of benzopyrans

### 1.3.4.3 The Nicholas reaction of optically active substrates

A stereospecific Nicholas Reaction was reported by Muehldorf in 1994. ${ }^{49}$ (Scheme 1.15 ) and showed that optically active product 65 , formed with limited racemisation. This could result from a Nicholas cyclisation reaction using chiral substrate 63 in an enantiospecific manner. The optically active propargyl alcohol 63 was used to control the selectivity. The author established that three criteria were important in controlling the levels of enantioselectivity, namely the size of the ring being formed, the substitution pattern of the aromatic ring and the type of

Lewis acid used. The chiral propargyl alcohol in 63 was formed using a three step procedure. This consisted of propargylation of the corresponding aldehyde 60, oxidation of the propargyl hydroxyl group 61 a ketone 62, using a DessMartin reaction, ${ }^{50}$ and then an asymmetric hydroboration using Alpine-Borane ${ }^{51}$ to afford 63.

60
61
62

Scheme 1.15: A stereospecific Nicholas reaction

### 1.4 Conjugate Addition Reaction

The conjugate addition reaction ${ }^{52}$ of organometallic reagents to $\alpha, \beta$-unsaturated compounds is one of the fundamental methodologies for the construction of $\mathrm{C}-\mathrm{C}$ bonds. ${ }^{53}$ It occurs with enones such as 66 and related compounds i.e. when a $\mathrm{C}=\mathrm{C}$ bond is conjugated to a $\mathrm{C}=\mathrm{O}$ bond and the nucleophile $\left(\mathrm{Nu}^{-}\right)$attacks at the $C=C$ instead of the $C=O$ to form the enolate 67 which then adds a proton to afford the extended carbonyl 68 (Scheme 1.16). ${ }^{54}$

## Scheme 1.16: A conjugate addition reaction

Addition reactions such as this have been used as key steps in the synthesis of numerous biologically active compounds ${ }^{55,56}$ and show wide applications because of the use of enone acceptors and the various donors types such as diorganozinc $\left(\mathrm{ZnEt}_{2}\right)^{57}$, triorganoaluminum ${ }^{58}$ and Grignard reagents. ${ }^{59}$

### 1.4.1 The mechanism of the conjugate addition reaction

The mechanism follows two steps:
(i) addition of the nucleophile to an enone
(ii) protonation of the enolate anion

The mechanisms for the non-catalytic organocuprate conjugate addition was reported by Krauss ${ }^{60}$ and involves the initial formation of an intermediate copperspecies via the $\pi$-complex 69. Formation of a magnesium enolate, 71 , via the copper (III) intermediate 70 provides a "soft" copper nucleophile. The formation of the Cu (III) complex, is reversible whereas the second step; formation of the enolate 71, is irreversible, making the overall reaction irreversible (Scheme 1.17). 61

Scheme 1.17: The pathway of the conjugate addition reaction with organocuprates

The principle of hard and soft Acid or Base (HSAB) ${ }^{62}$ suggests that hard acids favour binding to hard bases whereas soft acids prefer binding to soft bases. A Grignard reagent is identified as a hard nucleophile and therefore usually reacts with the carbonyl carbon atom, which is considered to be a hard electrophile in a 1,2-addition reaction. In the presence of copper (I), however, the Grignard/Copper reagent is considered to be "softer" and therefore undergoes 1,4-addition instead. During the process copper undergoes transmetallation with the Grignard reagent to give an organocopper species which provides a softer centre, compared to the Grignard reagent, which thus favours attack at the corresponding softer $\mathrm{C}=\mathrm{C}$ bond. Conjugate addition reactions nevertheless tend to compete with 1,2 -carbonyl addition reaction in $\alpha, \beta$-unsaturated carbonyl compounds. ${ }^{63}$ As a general rule in enones, the keto form is more stable than the enol form, however, from a synthesis point of view the enol form is more useful hence the interest in this chemistry. ${ }^{64}$

### 1.4.2 Asymmetric conjugate addition reaction

The first asymmetric conjugate addition to an $\alpha, \beta$-unsaturated compound via the use of chiral auxiliary technique ${ }^{65}$ a Grignard reagent as a nucleophile was reported in 1988. Other strategies made use of organocopper compounds containing chiral non-transferable groups such as chiral alkoxycuprates and amidocuprates. ${ }^{55,66}$ Corey reported ${ }^{67}$ enantioselectivities of over $90 \%$ by using a chiral ephedrine-derived lithium alkoxycuprate $\left((\mathrm{RO})_{2} \mathrm{CuLi}\right) .{ }^{43,53,68} \mathrm{~A}$ representative selection of catalysts are shown in Table 1.3.

Table 1.3: Chiral Catalyst for Conjugate Addition Reaction

| Catalyst type | substrate | ee\% | references |
| :---: | :---: | :---: | :---: |
|  |  | 4-14\% | 65 |
|  <br> 74 |  | 60\% | 69 |
|  <br> 75 |  | 0-76\% | 70,71 |
|  <br> 77 |  <br> 78 | 16-87\% | 69 |
|  <br> 79 |  | 4-92\% | 72 |

The first truly catalytic reagent 72 was developed by Lippard in 1988 for the conjugate addition of Grignard reagents to enones. ${ }^{65}$ This prototype catalyst was successful in carrying out an enantioselective 1,4-conjugate addition to cyclohex2 -en-1-one 73. Although the yield of the corresponding adduct 90 was acceptable (28-94\%) the enantiomeric excess were variable for instance when the R-group of the Grignard reagent was Ph the ee $=4 \%$ this rose to $14 \%$ when the R-group was changed to $n$-butyl. These values, while low, were comparable to earlier results in this area of catalysis and were nevertheless significant because they were achieved in a system where the chiral ligand-to-substrate ratio was only 0.04, about 200 times less than in recently published work where values of $88 \%$ enantiomeric excess were observed ${ }^{74}$ (Scheme 1.18).

Scheme 1.18: Asymmetric conjugate addition reaction

The chiral catalyst 74 was prepared in situ in the presence of the cuprate Cul. $\mathrm{SBu}_{2}$ and $n$ - BuLi and then examined for asymmetric conjugate addition to the enone 73. ${ }^{69}$ The highest enantioselectivity was reported with $n-\mathrm{BuMgBr}(\mathrm{ee} \%: 60$ $\%$ ) using $4 \mathrm{~mol} \%$ catalyst at $-78^{\circ} \mathrm{C}$.

The thiolate 75 was also reported as an active catalyst for asymmetric conjugate addition reactions with Grignard reagents and the enone 76 (Scheme 1.19). ${ }^{70}$ Data for the addition reaction with catalyst 75 are summarised in Table 1.4.

76

91

Scheme 1.19: Asymmetric conjugate addition in presence of catalyst 75

Table 1.4: Effect of Catalyst 75 on the Enantiomeric Excess

| $\mathbf{R}^{1}$ | $\mathbf{R}^{2}$ | $\mathbf{R}^{3}$ | $\mathbf{e e \%}$ |
| :---: | :---: | :---: | :---: |
| H | Me | Me | 76 |
| H | $\mathrm{i}-\mathrm{Pr}$ | Me | 72 |
| Cl | Me | Me | 69 |
| CN | Me | Me | 13 |
| OMe | Me | Me | 56 |
| H | $\mathrm{t}-\mathrm{Bu}$ | Me | 45 |
| H | Ph | Me | 0 |
| H | Me | $\mathrm{n}-\mathrm{Bu}$ | 45 |
| H | Me | $\mathrm{i}-\mathrm{Pr}$ | 10 |

The suggested intermediate 92 was formed from interaction of the catalyst 75 and Grignard reagent with the substrate 76 . The catalyst 75 first reacts with $\mathrm{R}^{3} \mathrm{MgBr}$ and the enone bonded with both the copper and magnesium. The double bond is coordinated to copper and the oxygen atom binds to magnesium (Figure 1.18). ${ }^{71}$

92
Figure 1.18: The proposed intermediate between catalyst 75, Grignard reagent and substrate 76

Zhou and Pfaltz ${ }^{69}$ modified the structure of catalyst 75 to the oxazoline 77. This catalyst showed the highest levels of enantiomeric excess in an asymmetric conjugate addition reaction. This catalyst was evaluated against
several enones such as 78 and also with various Grignard reagents in yields of 30-70\% (Scheme 1.20).

Scheme 1.20: Asymmetric conjugate addition in presence of the catalyst 77

Sammakia ${ }^{73}$ reported high enantioselectivities in the conjugate addition to the enone 72 using $12 \mathrm{~mol} \%$ of the chiral catalyst 81 in conjunction with $10 \mathrm{~mol} \%$ of Cul in $\mathrm{Et}_{2} \mathrm{O}$. The highest enantiomeric excess ( $83 \%$ ) was reported for the addition of the $n-\mathrm{BuMgCl}$ to 72 in the presence of additive such as HMPA, TMSCI or Mel.
A breakthrough in this area of catalysis came in 2004 when Feringa ${ }^{52,74,80}$ synthesised the novel ligands Josiphos 82 and Taniaphos 84 as chiral diphosphines suitable for the 1,4 -addition reaction to enone. These catalysts were then used by several groups in 1,4-asymmetric conjugate reactions. ${ }^{69,81}$ These ferrocene-based ligands provided high enantioselectivities in conjunction with the cyclic enone 73 with enantiomeric excess up to $96 \%^{52}$ (Scheme 1.20). Their results indicated that these ligands in combination with $\mathrm{P}, \mathrm{S}, \mathrm{Se}, \mathrm{N}$ or O donor atoms extend the use of copper and magnesium organometallic species in the highly active and selective 1,4-conjugate addition of a wide range of substrates. ${ }^{72 a, b, 73,82}$ The data derived from an investigation into the use of various Grignard reagents are shown in Table 1.5

Table 1.5: Enantioselective Conjugate Addition to 73 with Catalysts 82 and 84

| RMgBr | L | Ratio of $1: 4$ to 1:2 addition | $\mathrm{e} \%^{\mathrm{a}}$ |
| :---: | :---: | :---: | :---: |
| EtMgBr | 84 | 95:5 | 96 |
| MeMgBr | 84 | 83:17 | 90 |
| ${ }^{\mathrm{n}} \mathrm{PrMgBr}$ | 84 | 81:19 | 94 |
| "BuMgBr | 84 | 88:12 | 96 |
| ${ }^{\prime} \mathrm{PrMgBr}$ | 84 | 78:22 | 1 |
| ${ }^{\prime} \mathrm{BuMgBr}$ | 84 | 62:38 | 33 |
| (2-methyl) BuMgBr | 84 | 76:24 | 95 |
| $4-\mathrm{Cl}-\mathrm{BuMgBr}$ | 84 | 79:21 | 85 |
| ${ }^{\text {i }} \mathrm{PrMgBr}^{\text {b }}$ | 82 | 99:1 | 54 |
| ${ }^{\prime} \mathrm{BuMgBr}^{\text {b }}$ | 82 | 99:1 | 92 |
| EtMgBr ${ }^{\text {b }}$ | 82 | 99:1 | 56 |

Analysis of the data in Table 1.5 reveals that Josiphos 82 controlled the enantioselectivity in the conjugate addition reaction to 2-cyclohexen-2-one 73 with good to excellent enantiomeric excess (54-92\%) and very high levels of 1,4regioselectivity. Taniaphos 84 , on the other hand provided higher levels of enantiomeric excess (90-96\% apart from one example) but lower levels of 1,4regioselectivity. ${ }^{74}$ Acyclic enones, such as 83 were also examined in an enantioselective conjugate addition reaction with 82 and 84 (Scheme 1.21). This resulted in the synthesis of $\beta$-substituted linear ketones, 93 , and the corresponding 1,2-adduct 94. The best ratio (93:94) was $99: 1$ and also the best enantiomeric excess was $90 \%$ with EtMgBr in the presence of $\mathrm{CuBr} . \mathrm{SMe}_{2}$ at -78 ${ }^{\circ} \mathrm{C}$.

Scheme 1.21: Asymmetric conjugate addition to acyclic enones in presence of chiral catalyst 82 or 84

A tentative model for the stereocontrol was suggested by Feringa ${ }^{52}$ who suggested that chelation occurs through the magnesium atom with the carbonyl moiety of the enone as well as between the enone double bond and the copper centre shown in 95. Formation of a $\sigma$-bond between the Cu (III) species and the $\beta$-carbon as well as between magnesium and the oxygen generates the enolate 96 in situ, via a seven-membered chair-like ring transition state. This sets up the absolute configuration that facilitates attack of the methyl nucleophile from the copper (III) species to the $\beta$-carbon of the enone. The transfer of the methyl group is the rate-determining step and is the step where the enantioselective product 97 is formed (Figure 1.19). ${ }^{52}$

95

96
97

Figure 1.19: Feringa's model for the enantioselective CA of Grignard reagents ${ }^{52}$
Monodentate and bidentate chiral diphosphine ligands such as Trost ligand $\mathbf{8 5} \mathbf{5}^{\mathbf{7 5}}$, BINAP $86^{76}$, DuPhos $\mathbf{8 7}{ }^{77}$ have been employed in a variety of asymmetric conjugate addition reactions. In general the reported enantiomeric exces are quite low $(5-28 \%)$ which Feringa ${ }^{74}$ suggests might be attributed to a mismatch between for instance the diphosphine ligands of the catalysts with the metal atom ( $\mathrm{Cu}, \mathrm{Mg}, \ldots$ ) therefore efficiency would be very low. The chiral catalyst containing ferrocenyl-based diphosphine ligands such as MandyPhos $\mathbf{8 8}^{78}$ and WalPhos $89^{79}$ have been shown to produce high levels of enantioselectivity ( $45-70 \%$ ), (Table 1.3).

### 1.5 Alkynylation of an aldehyde

Optically active propargyl alcohols can be found in many natural products and bioactive compounds such as ethisterone 98 (Figure 1.20) and are also widely used as precursors in organic synthesis.

98
Figure 1.20: Bioactive propargyl alcohol 98

The propargyl alcohol 99 was converted to an allene 100 which was then converted to the furan derivatives with a yield $(99 \%))^{83}$

Scheme 1.22: Furan synthesis

The 1,2-addition of an alkyne to an aldehyde is another variation of an organometallic reaction. ${ }^{84}$ The synthesis of a tertiary alcohol from the reaction of an alkynyl Grignard reagent with a ketone is a standard method which has been applied in a variety of applications. ${ }^{85}$ A typical example is the addition of a alkyne such as 103 to aldehyde 102 to afford the propargyl alcohol 104 (Scheme 1.23). ${ }^{86}$

Scheme 1.23: Synthesis of a racemic mixture of the propargyl alcohol 104

In recent years, however, there has been a growing interest in the synthesis of optically active propargyl alcohols for use in asymmetric synthesis.

### 1.5.1 Asymmetric alkynylation

Asymmetric alkynylation reactions are such important transformations in contemporary organic synthesis that several reviews have been published over the past few years. ${ }^{87}$ The enantioselective alkynylation of aldehydes has been reported extensively in the literature using a variety of a chiral catalysts, chiral pool molecules and chiral auxiliaries. ${ }^{87 a, b}$
Yamamoto ${ }^{88}$ reported a highly syn diastereoselective (85:15, syn:anti) synthesis of steroidal propargyl alcohol 107 by treating of the steroidal aldehyde 105, a chiral substrate, with the stannylacetylene 106 (Scheme 1.24).

Scheme 1.24: The syn-diastereoselective synthesis of steroidal propargyl alcohol 107

A highly enantioselective, (ee $=97 \%$ ), alkynylation of benzaldehyde was reported with the use of the chiral oxazaborolidine 110 in the presence of the phenylacetylene dimethylborane 109 formed in situ from bromodimethylborane and the corresponding alkynylstannane 108 via the transition state 112 (Scheme 1.25) ${ }^{89}$

112
Scheme 1.25: The enantioselective alkynylation of benzaldehyde using oxazaborolidine 110

BINOL ligands have been shown to give high enantioselectivities (up to $96 \%$ ee) and yields of $85 \%$ in asymmetric alkynylation reactions (Scheme 1.26). ${ }^{23 \mathrm{~d}, 90}$

Scheme 1.26: Asymmetric alkynylation using (S)-BINOL and sulphonamide

An efficient system for the enantioselective alkynylation of aromatic and aliphatic aldehydes 113 with terminal alkynes 114 using stoichiometric amounts of (+)-Nmethylephedrine 116 and $\mathrm{Zn}(\mathrm{OTf})_{2}$ have been reported (Scheme 1.27). ${ }^{91-92}$

Propargyl alcohols, 115 have been obtained with enantiomeric excess in the range $92-99$ \%. This is also known as the Carreira reaction.

Scheme 1.27: Alkynylation of aldehyde 113 with a terminal alkyne 114 using ( + )- Nmethylephedrine 116 as a ligand (Carreira reaction)

The same investigators were eventually able to carry out the reaction using catalytic amounts of $\mathrm{Zn}(\mathrm{OTf})_{2}$. The catalyst system was excellent for aliphatic aldehydes but was less effective for aromatic aldehyde (Table 1.6).

Table 1.6: Enantioselective Additions of Terminal Alkyne to Aldehyde ${ }^{91 a, b}$

| Aldehyde(113) | Alkyne(114) | Time (h) | Yield\% | ee \% |
| :--- | :--- | :---: | :---: | :---: |
| 113a $c-\mathrm{C}_{6} \mathrm{H}_{11}$ | 114a Ph | 1 | 99 | $96(\mathrm{R})$ |
| 113b iso-Pr | 114b $\mathrm{Ph}\left(\mathrm{CH}_{2}\right)_{2}$ | 2 | 90 | $99(\mathrm{R})$ |
| 113c $\mathrm{PhCH}=\mathrm{CH}$ | 114c $\mathrm{Ph}\left(\mathrm{CH}_{2}\right)_{2}$ | 20 | 39 | $80(\mathrm{R})$ |
| 113d tert-Bu | $114 \mathrm{~d} \mathrm{Ph}\left(\mathrm{CH}_{2}\right)_{2}$ | 2 | 84 | $99(\mathrm{R})$ |
| 113e Ph | 114 e Ph | 20 | 53 | $94(\mathrm{R})$ |
| $113 \mathrm{me}_{3} \mathrm{CCH}_{2}$ | 114 fh | 2 | 90 | $97(\mathrm{R})$ |

The data in Table 1.6 show that the best yields and enantiomeric exces were obtained from the reaction of iso-propionaldehyde 113b and benzylalkyne 114b and the lowest yield and enantiomeric excess were obtained from the reaction of the 113c and alkyne 114c. The absolute configuration of the products was established by correlation with known compounds or by analogy. Thus when (-)-$N$-methylephedrine was used as the ligand, the opposite enantiomer was obtained in comparable yields and enantiomeric excess. The transition state for this reaction, 117, was proposed by Carreira (Figure 1.21).

117
Figure 1.21: The transition state, 117 proposed by Carreira ${ }^{91 a, 91 c}$

The selectivity is then proposed to arise by chelating the zinc with two alkynes with the nitrogen and oxygen atoms of N -methylephedrine therefore the aldehyde is held between two alkynes and shielded by the chiral ligand as showed in 117.

The asymmetric addition of allylzinc reagents to alkynyl ketones in the presence of a bisoxazoline catalyst, 118 was recently reported. ${ }^{93}$ The corresponding propargyl alcohol 120 were obtained in 54-93 \% yield and moderate to high enantiomeric excess 25-99\% (Scheme 1.28).

Scheme 1.28: Asymmetric addition of allylzinc reagents to alkynyl ketones

### 1.6 Chiral auxiliary

Chiral auxiliary technology has become one of the most powerful strategies for controlling stereoselectivity in an organic synthesis. ${ }^{94}$ A chiral auxiliary is a molecule that when added to an achiral compound facilitates an asymmetric reaction to occur by directing the reaction and controlling the 3-D structure of the intermediate which results in the formation of the new chiral center. As part of
this study an attempt was made to affect the synthesis of a novel chiral aldehyde as a precursor to an intramolecular asymmetric Nicholas reaction. Therefore it was considered the application of chiral auxiliary technology. The most effective chiral auxiliaries have been based upon chiral oxazolidinones such as $122 .{ }^{95}$ Most chiral oxazolidinones are prepared from the corresponding amino acid 121, a chiral pool molecule (Scheme 1.29). ${ }^{96}$

Scheme 1.29: Synthesis of chiral auxiliary from amino acid

There are three fundamental features of a good chiral auxiliary. First, it must be readily attached under mild experimental conditions, secondly it should be robust and mediate a highly stereoselective transformation and thirdly it must be easily removed without racemization of the newly-created stereogenic center(s), and be separable from the cleaved product. ${ }^{94 a}$ The class of chiral oxazolidinone, such as 122 and 123 (Figure 1.22) were first introduced by Evans in $1981^{94 b}$ and have been used extensively since they readily comply with these three points above. ${ }^{94 a, 97}$

123
Figure 1.22: Evan chiral oxazolidinone

The use of a prolinol amine 124 (chiral amino-alcohol) was one of the first examples of Evan's use of an azolidinone in asymmetric synthesis. The acylation reaction occurred to afford 125 which upon exposure to lithium diisopropylamide (LDA) provided the prolinol amide enolate 126 (Scheme 1.30). ${ }^{98}$ Benzylation of the lithium enolate followed by cleavage of the chiral auxiliary provided the chiral acid 128 in $92 \%$ yield and an enantiomeric excess of $69 \% .{ }^{98}$

92 \% yield, ee 69 \%
Scheme 1.30: Synthesis of an Evan's azolidinone using prolinol amide 124

Evans also developed the asymmetric alkylation reaction of chiral oxazolidinones using sodium as well as lithium bases [LDA or $\operatorname{NaN}(T M S)_{2}$ ] which cleanly converted the imides 129 and 132 into the respective (Z)-metal enolates 130 and 133 in quantitative yields around $94-99 \%$. The final products optically active carboxylic acids were obtained from the cleavage of the chiral auxiliaries 131 and 134 (Scheme 1.31). ${ }^{99}$

Scheme 1.31: Asymmetric alkylation of chiral oxazolidinones via (Z)-metal enolates

One of the earliest applications of chiral auxiliary by Evans was in his synthesis of the intermediates 135 and 136. These were key components in the synthesis of the polyether antibiotic monensin 137. ${ }^{100}$ The optically active compounds were achieved in 60\% yield and $98 \%$ isomeric purity for 136 and $52 \%$ yield and $90 \%$ enantiomeric excess for 135 (Figure 1.23). ${ }^{100}$

135

136

137

Figure 1.23: Structure of monensin 137 and two precursors

In general chiral oxazolidinone auxiliaries control the alkylation reaction to produce the inverse configuration to the auxiliary itself. For example the alkyl oxazolidine 139 has an (R)-configuration in the newly formed chiral center due to the chelated Z-form lithium enolate in the precursor (Scheme 1.32) ${ }^{95,100}$

138
139

Scheme 1.32: Alkylation of the oxazolidinone auxiliary

Generally, $N$-butanoyloxazolidinones such as 138 form the Z-lithium enolate 140 selectively rather than E-form and this chelate then controls the subsequent alkylation reaction as preferential attack occurs from the face of the enolate 141 that is opposite the bulky isopropyl group (minimization of steric interactions) (Figure 1.24)

Figure 1.24: Evans imides form Z-lithium enolates

In conclusion because four different asymmetric synthetic strategies were attempted in this project, these have been summerised in this Introduction:
(i) Chiral catalyst ( + )-N-methylephedrine for the asymmetric alkynylation reaction
(ii) Josiphos 82 and Taniaphos 84 for the asymmetric conjugate additions.
(iii) Chiral pool synthesis for the formation of novel chiral propargylic alcohols
(iv) Chiral auxiliary technology

## 2 Results and Discussion

### 2.1 Introduction and Aims

The aim of this study was to undertake an investigation into an asymmetric Nicholas reaction. The approach in attempting to achieve this goal involved a number of different methodologies that are available to synthetic organic chemists:
(i) The use of a chiral catalyst (section 2.3.1)
(ii) The use of chiral substrate (chiral pool) (section 2.6)
(iii) The use of chiral auxiliary technology (section 2.7)

At the commencement of this study however it was decided to explore an interesting tandem reaction that had previously been investigated in the Kingston University laboratories, but not optimised. A tandem reaction is one in which several bonds are formed in sequence without changing the reaction conditions. ${ }^{101}$

The reaction sequence is shown in Scheme 2.1.

Scheme 2.1: Tandem cyclisation reaction
The expected decalone 143, resulting from a Nicholas cyclisation reaction, was not isolated however the tricyclic compound 144 was obtained instead. It was deduced that during the decomplexation reaction an additional tandem cyclisation occurred to afford the tricyclic compound 144. This was an unprecedented sequence of reactions. ${ }^{44}$ Optimising this chemistry would provide
a sound introduction to the later more challenging techniques that would be required. The initial investigation focussed upon the non-asymmetric tandem reaction sequence and once this was optimised the asymmetric synthesis would be undertaken.

### 2.2 The tandem cyclisation reaction

The cobalt complex 47 was synthesised by an intermolecular Nicholas reaction between the $O$-silylenol ether 46 and the complexed propargylic diacetal 45 shown in the Scheme 2.2. The O-silylenol ether 46 was formed by the conjugate addition reaction of cyclohexen-1-one 73 with the cuprate-derivative of 5 -bromo-2-methylpent-2-ene 145.

Scheme 2.2: Synthesis of the cyclisation precursor 47

### 2.2.1 Conjugate Addition Reaction

The 1,4-conjugate addition reaction in the presence of copper catalyst was described in section 1.4.
In a model study it was first attempted the conjugate addition of ethylmagnesium bromide with 2-cyclohexen-1-one 73 entrapping the corresponding enolate as an O-silylenol ether derivative 46a (Scheme 2.3). ${ }^{102}$

Scheme 2.3: 1,4-conjugate addition of Grignard reagent with 2-cyclohexen -1- one

This involved the addition of TMSCI and the enone 73 to a solution of ethylmagnesium bromide and $\mathrm{CuBr} . \mathrm{Me}_{2} \mathrm{~S}$ maintained at a temperature of $-78^{\circ} \mathrm{C}$ under an atmosphere of nitrogen. The reaction mixture was quenched when the solution acquired a dark blue coloration. Analysis by tlc showed a fast moving compound with an $R_{f}=0.81$ (petroleum spirit: ether 80: 20). Purification by flash chromatography on silica gave the desired enone 46a in a yield of $90 \%$ as a colourless oil. IR analysis revealed the loss of the carbonyl peak ( $C=O$, stretch) of enone 73, at $1720 \mathrm{~cm}^{-1}$, and the presence of peaks at 1095.1, 1186.1, 1251.6 $\mathrm{cm}^{-1}$ attributed to $\mathrm{O}-\mathrm{Si}$ and $\mathrm{Si}\left(\mathrm{CH}_{3}\right)_{3}$ bonds. The ${ }^{1} \mathrm{H}$ NMR spectrum showed relevant resonance at $\delta 0.00 \mathrm{ppm}$, attributed to $\mathrm{Si}\left(\mathrm{CH}_{3}\right)_{3}$ and a doublet at $\delta 4.9$ ppm attributed to the $=\mathrm{CH}$ proton. As the eventual aim in this present study was to attempt an asymmetric conjugate addition of the cuprate derivatives of 46 to enone 73 , using an appropriate chiral catalyst, it was attempted to optimise the conjugate addition using a number of alkyl/alkenyl halides. The corresponding Osilylenol ethers 46a-f were obtained in good to excellent reproducible yields. (Table 2.1)

Table 2.1: Data of Conjugate Reaction

|  |  | 82 |

### 2.3 Nicholas Reactions

### 2.3.1 Intermolecular Nicholas reaction

Having successfully synthesised a range of O-silylenol ethers 46a-f the project focussed on the intermolecular Nicholas reaction between the O-silylether 46 and the cobalt cluster 45 (Scheme 2.2). This was carried out by stirring a equimolar mixture of the cobalt cluster 45 and O -silylenol ether $\mathbf{4 6}$ in a flame-dried two-neck flask containing dry DCM maintained at a temperature of $-78^{\circ} \mathrm{C}$. Boron trifluoride diethyletherate $\left(\mathrm{BF}_{3} . \mathrm{OEt}_{2}\right)$ was added and the solution was left to stir for 3 hours at $-78{ }^{\circ} \mathrm{C}$ before allowing it to reach room temperature. TLC analysis of the reaction mixture confirmed the presence of a new compound with $R_{f}=0.6$ (Petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether $70: 30$ ). After purification the desired complex 47 was obtained in a yield of $85 \%$ IR analysis (Figure 2.1) disclosed the ketone carbonyl peak of at $1712.13 \mathrm{~cm}^{-1}$ as well as peaks at 2025.76, 2054.07 and $2094.31 \mathrm{~cm}^{-1}$ attributed to the cobalt carbonyl moieties.

Figure 2.1: IR spectrum of cobalt complex 47

As spectral characterisation of cobalt complexes such as 47 can sometimes be thwarted by the presence of paramagnetic cobalt species, that lead to signal broadening and loss of acuity in the NMR spectra, a sample of the complex 47 was decomplexed to afford 146.

Scheme 2.4: Decomplexation of 47

The ${ }^{1} \mathrm{H}$ NMR spectrum for 146 confirmed the structure of the product (Figure 2.2). ${ }^{1} \mathrm{H}$ NMR showed a multiplet at $\delta 5 \cdot 15-5.10 \mathrm{ppm}(1 \mathrm{H})$ attributed to $\underline{H} C=C$, a doublet of doublets at $\delta 4.10 \mathrm{ppm}(1 \mathrm{H}, J=8.0,1.9 \mathrm{~Hz})$ attributed to CHOEt, a multiplet at $\delta 3.6-3.5 \mathrm{ppm}(1 \mathrm{H})$ and a multiplet at $\delta 3.25-3.18 \mathrm{ppm}(1 \mathrm{H})$ attributed to $\mathrm{CH}_{2} \mathrm{CH}_{3}$. The terminal alkyne proton showed a broad singlet at $\delta$ 2.55 ppm . A multiplet at $\delta 2.38-2.45 \mathrm{ppm}(2 \mathrm{H})$ attributed to $\mathrm{CH}_{2} \mathrm{C}=\mathrm{O}, 10$ proton showed multiplets at different resonaces, at $\delta$ 2.13-1.33 ppm attributed to four $\mathrm{CH}_{2}$ and two CH ); 2 singlets at $\delta 1.65 \mathrm{ppm}$ and 1.69 ppm are attributed to $(6 \mathrm{H}, 2$ $\left.\mathrm{x}=\mathrm{C}\left(\mathrm{CH}_{3}\right)_{2}\right)$; a triplet at $\delta 1.15 \mathrm{ppm}(3 \mathrm{H}, J=7.2 \mathrm{~Hz})$ attributed to $\mathrm{CH}_{2} \mathrm{CH}_{3}$.

Figure 2.2: ${ }^{1} \mathrm{H}$ NMR spectrum of 146

### 2.3.2 Intramolecular Nicholas Reaction

The corresponding intramolecular Nicholas reaction was achieved by adding Lewis acid $\mathrm{BF}_{3}$. $\mathrm{Et}_{2} \mathrm{O}$ to a solution of 47 dissolved in DCM at $-78^{\circ} \mathrm{C}$. Tlc analysis after 3 h showed the presence of a new compound with an Rf 0.5 (petroleum ether: ether 70:30). Decomplexation, of the dicobalt hexacarbonyl cluster, was achieved by an oxidative addition reaction using CAN at $0^{\circ} \mathrm{C}$. GC-MS analysis of the product showed only one peak with a mass of m/z 218 and extensive NMR studies confirmed the structure was 144 obtained in a yield of $\quad 35 \%$ from 47 . The spectra were in agreement with those previously published. ${ }^{44}$ Thus from the ${ }^{1} \mathrm{H}$ NMR spectrum (Figure 2.3) resonances at $\delta 0.65$ and $0: 85 \mathrm{ppm}$ showed the existence of the dimethyl group and two olefinic resonances were seen at $\delta 5.42 \mathrm{ppm}(1 \mathrm{H}, \mathrm{dd}, J=5.8,4.2 \mathrm{~Hz})$ and $\delta 5.72 \mathrm{ppm}$ ( $1 \mathrm{H}, \mathrm{d}, J=5.8 \mathrm{~Hz}$ ). Of significance was a complete absence of a resonance for the terminal alkynyl-H hydrogen at approximately $\delta 2.5 \mathrm{ppm}$. The ${ }^{13} \mathrm{C}$ DEPT revealed the presence of two $\mathrm{sp}^{2}$ hybridised carbon atoms $(=\mathrm{CH})$ at $\delta 130.86$ and $\delta 142.35 \mathrm{ppm}$ and four methine (C-H) carbon atoms between $\delta 46.65 \mathrm{ppm}$ and 60.50 ppm. ${ }^{44}$

Figure 2.3: ${ }^{1} \mathrm{H}$ NMR spectrum of tricycle 144

### 2.4 Asymmetric Tandem Reaction

The reactions exposed in the previous sections were repeated asymmetrically. This envisaged that the reaction sequence began with the use of a chiral catalyst to control the stereochemistry of the initial conjugate addition step. This would provide enantio enriched O-silylenol ether 147. With the C-3 chiral centre in 147 controlled this envisaged that it would then influence the stereochemical outcome of the corresponding intermolecular Nicholas reaction to provide 148 (Scheme 2.5)

Scheme 2.5: Asymmetric intermolecular Nicholas reaction

### 2.4.1 Chiral catalyst

A survey of the literature highlighted two potential catalyst candidates for the asymmetric conjugate addition reactions ${ }^{59 \mathrm{~g}, 74}$ these are Josiphos 82 and Taniaphos 84 (Figure 2.4).

82

84

Figure 2.4: Chiral catalyst Josiphos 82 and Taniaphos 84

According to the literature these have been used to good effect and produced enantiomeric excess of $80-96 \%^{599,74}$ in conjugate addition reactions to substrates such as enone 73. The enantioselectivity observed has been rationalised upon the basis that the ligands cover one face of the substrate allowing attack of the cuprate from the other face. ${ }^{52}$

### 2.4.2 Asymmetric 1, 4-conjugate addition

A model asymmetric conjugate addition reaction was carried out between enone 73 and the organometallic species in the presence of either catalyst 82 or catalyst 84 (Scheme 2.6).

Scheme 2.6: Asymmtric 1,4-conjugate addition in presence of catalyst 82 or 84
In the literature procedure the compound isolated from the initial asymmetric conjugate addition was the ketone, equivalent of 149 rather than the corresponding 0 -silylenol ether derivative 150 and so there was no assurance that these catalysts would perform in the desired way.

In the initial attempt at the synthesis of $\mathbf{1 5 0}$ the literature procedure was followed, however, TMSCI was added in order to quench the enol form. The isolated yield for this was low and purification very challenging. It was then decided to initially isolate the chiral ketone 149 and then generate the enolate derivative 150 in a second step. To prepare the copper complex (Scheme 2.7) copper bromide
dimethyl sulfoxide ( $5 \mathrm{~mol} \%$ ) was mixed with Josiphos 82 or Taniaphos 84 ( 6 mol $\%$ ) in dry THF at $-78^{\circ} \mathrm{C}$ under a nitrogen atmosphere. Ethylmagnesium bromide was then added to form a chiral copper complex in $5 \%$ catalytic amount, where upon cyclohex-2-en-1-one 73 was added to this mixture and the product isolated. The optical active ketone 149 was synthesised in $98 \%$ yield, with an enantiomeric excess of $70 \%$ which was determined by divided observed rotation by maximum rotation. The specific rotation $[a]_{D}^{21}=+11^{\circ}(c=2.5 \%$ in chloroform) compared favourably with the literature value for the enantiomer of 150 is $-10.3^{\circ}$ ( $\left.\mathrm{c}=2.9 \% \mathrm{CHCl}_{3}\right)^{599,103}$

Scheme 2.7: Copper complex from mixture of chiral catalyst $\mathbf{8 2}$ or 84 with copper catalyst and Grignard reagent

The same reaction conditions were used with the alkenyl Grignard derivative of 145 to afford the desired ketone 151 (Scheme 2.8)

Scheme 2.8: Asymmetric 1,4-conjugate addition

This was obtained in an excellent yield of ( $92 \%$ ) however unlike ketone 149 it was devoid of any optical activity. This is despite the fact that both Josiphos $\mathbf{8 2}$ and Taniaphos 84 are reported to be potent chiral catalysts for asymmetric conjugate addition reactions of aromatic, alkyl and alkenyl Grignard reagents with cyclohexenones. ${ }^{59,74}$ It would appear however that for longer chain substrates these were not effective catalysts. Having been thwarted by the poor performance of these catalysts an alternative strategy involving the conjugate addition of a benzyl derivative was adopted.

### 2.4.3 Retrosynthetic analysis

An alternative strategy to achieve the goal was in the synthesis of the tricyclic compound 152 formed in an analogous sequence of reactions that begins with the conjugate addition of benzylmagnesium bromide to the enone 73 (Scheme 2.9).

Scheme 2.9: Retrosynthesis of tricyclic compound 152

The first step was to achieve the synthesis of the O-silylenol ether 46e which was synthesised using standard reaction conditions (Scheme 2.10).

Scheme 2.10: 1,4-conjugate addition of Grignard reagent with 2-cyclohexen-1-one 73

Analysis of the reaction mixture by tlc showed the presence of a new compound $\left(R_{f}=0.3\right.$ hexane: diethyl ether $\left.70: 30\right)$ and a complete absence of the starting
material. The new compound was isolated ( $96 \%$ ), purified and spectroscopically analysed. GC-MS showed one peak with $\mathrm{m} / \mathrm{z} 260$ and the ${ }^{1} \mathrm{H}$ NMR spectrum revealed a multiplet at $\delta 7.34-7.26 \mathrm{ppm}(5 \mathrm{H})$ and a doublet of triplets at $\delta 4.87$ $\mathrm{ppm}(1 \mathrm{H}) J=7.0,2.3 \mathrm{~Hz}$ consistent with the vinyl proton. A single sharp resonance at $\delta 0 \mathrm{ppm}(9 \mathrm{H})$ confirmed the presence of the TMS group. Reaction of diethoxypropyne, dissolved in DCM, with dicobalt octacarbonyl gave the corresponding complex 45. The reaction may be readily monitored by the evolution of $\mathrm{CO}_{(9)}$ from the reaction mixture and is assumed to have reached completion when the bubbling ceases. The product 45 was then isolated in a quantitative yield as dark red oil. IR analysis showed a cluster of peaks at 2023.8 $\mathrm{cm}^{-1}$ attributed to cobalt hexacarbonyl. An intermolecular Nicholas reaction between 45 and $46 e$ was carried out to synthesise 154 . This was undertaken by the dropwise addition of $\mathrm{BF}_{3} . \mathrm{OE}_{2}$, as a Lewis acid, to a mixture of 46 e and the cobalt complex 45 at $-78{ }^{\circ} \mathrm{C}$. TLC analysis of the reaction mixture, after 3 h , showed the presence of a new compound as a dark red spot on the tlc plate ( $\mathrm{R}_{\mathrm{f}}$ $=0.51$ petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether $\left.70: 30\right)$. The reaction was quenched and the desired cobalt complex 154 was isolated in a yield of $65 \%$. The IR spectrum of 154 in Figure 2.5, clearly shows the presence of the cobalt carbonyl cluster at $2000 \mathrm{~cm}^{-1}$ as well as the keto-carbonyl at $1712 \mathrm{~cm}^{-1}$.

Figure 2.5: IR spectrum of complex 154

The corresponding ${ }^{1} \mathrm{H}$ NMR spectrum confirmed the structure of 154 with a multiplet at $\delta 7.39-7.09 \mathrm{ppm}(5 \mathrm{H})$ attributed to the aromatic protons and a doublet at $\delta 4.92 \mathrm{ppm}(J=9.0 \mathrm{~Hz})$ attributed to the CHCHOEt . The two methylene protons $\mathrm{OCH}_{2} \mathrm{CH}_{3}$ resonate at $\delta 4.04-3.87$ and $3.59-3.34 \mathrm{ppm}(1 \mathrm{H})$ and a multiplet at $\delta 3.60-3.55 \mathrm{ppm}(1 \mathrm{H})$. From $\delta 2.55-1.30 \mathrm{ppm}$ there is a
complex multiplet intergrating for 11 protons and a triplet peak at $\delta 1.30 \mathrm{ppm}$ attributed to $\mathrm{CH}_{3}$. Decomplexation 154 was accomplished using CAN to afford the decomplexed derivative 154a for detailed analysis.

The intramolecular Nicholas reaction was obtained by slow dropwise addition of a stoichiometric amount of Lewis acid at $0^{\circ} \mathrm{C}$ to the complex 154. The reaction was very rapid and tlc analysis after 5 minutes showed the presence of a new compound $R_{f}=0.7$ (petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ : diethyl ether $\left.70: 30\right)$. The desired tricyclic compound 153 was obtained as a red oil in a yield of $40 \%$. ${ }^{1}$ H-NMR of cobalt complexes may sometimes be obtained, but they often require careful serial dilutions of the sample in order to obtain a spectrum with well defined resonances. The presence of paramagnetic impurities tend to lead to signal broadening and poor definition nevertheless the NMR of complex 153 showed the correct number of protons at the appropriate chemical shifts but the peaks were too broad to analyse the multiplicities. The oxidative decomplexation of 153 was achieved by cooling a methanolic solution to $0^{\circ} \mathrm{C}$ before the addition of a solution of CAN dissolved in methanol. Tlc analysis revealed a colourless compound 152 with an $R_{f}=0.6$ (hexane: ethyl acetate $85: 15$ ), in a yield of $38 \%$ (Scheme 2.11)

Scheme 2.11: Decomplexation of tricyclic compound 153
${ }^{1} \mathrm{H}$ NMR analyse was used to confirmed the structure of 152 (Figure 2.6). The benzylic methine proton resonated at $\delta 4.0 \mathrm{ppm}$, the $\alpha$-methine proton at 2.9 ppm and the terminal alkynyl proton at $\delta 2.04 \mathrm{ppm}$.

Figure 2.6: ${ }^{1} \mathrm{H}$ NMR spectrum of 152

In contrast to the cyclisation of $\mathbf{4 7}$ shown (Scheme 2.1) the cyclisation of 154 was actually a variant of a Friedel-Craft alkylation using the Nicholas cation. With this in mind it was decided to focus upon this reaction in more detail in a simpler model system. In this approach the asymmetry is not derived from an asymmetric conjugate addition, as described above, but more directly from the synthesis of an optically active propargyl alcohol.

### 2.5 Asymmetric Nicholas reaction from an optically active propargyl alcohol

Muehldorf ${ }^{49}$ had showed that the use of a Friedel-Craft variation of a Nicholas reaction could be put to good use in the enantiospecific synthesis of 156 (Scheme 2.12).

Scheme 2.12: Enantioselective Nicholas cyclisation

In his approach the optically active propargyl alcohol was formed in two steps from the racemate via oxidation to the ketone followed by a Midland ${ }^{104}$ asymmetric reduction using Alpine-Borane. It was envisaged that this methodology could be applied to the asymmetric synthesis of benzopyrans such as 158 (Scheme 2.13). The interest in this class of molecule lay in their antihypertensive activity. ${ }^{16-18}$ In addition it was envisaged that the optically active propargyl alcohol 157 could be accessed directly by a Carreira asymmetric alkynylation ${ }^{9 a, 91 a, 92 b}$ of an aldehyde. Furthermore it was reasoned that the phenolic oxygen, present in 157, would activate the aromatic ring for the
cyclisation to occur without recourse to the C-3, C-4 methoxy groups used by Muehldorf in his synthesis.

Scheme 2.13: Asymmetric cyclisation of optically active propargyl alcohol 157

The most common approach to the synthesis of propargyl alcohols is the direct reduction of alkynyl ketones ${ }^{87 \mathrm{~b}-\mathrm{d}}$ or the alkynylation of an aldehyde by organometallic reagents. ${ }^{87,105}$ This last approach has a strategic advantage because it forms a new C-C bond with related creation of a stereogenic center in a single transformation, while in the approach used by Muehldorf the C-C bond and the new chiral centre are formed separately.

For the initial synthesis of a racemic propargylic alcohol 159, the alkynylation of aldehyde 160 using a stochiometric amount of a Grignard reagent such as ethynyl magnesium bromide in an anhydrous organic solvent may be employed (Scheme 2.14). ${ }^{87 a-d}$ For optically active propargyl alcohols the Carreira reaction ${ }^{91 a, 92 b}$ may be applied between aldehyde 160 and an alkyne in the presence of N -methylephedrine as a chiral catalyst.

Scheme 2.14: Retrosynthesis of propargyl alcohol 159

Aldehyde 160 can be obtained from the deprotection of the corresponding dioxolane 161, which itself is obtained from the Williamson ether synthesis of phenol 162 and the dioxolane 163.

Scheme 2.15: Retrosynthesis of the aldehyde 160

### 2.5.1 O-Alkylation (Williamson ether synthesis)

A Williamson reaction ${ }^{106}$ was carried out between phenol 162 and 2-(2-bromoethyl)-1,3-dioxolane 163. Potassium carbonate, in the presence of potassium iodide, was stirred for 10 minutes at an ambient temperature before phenol 162 was added. Tlc analysis of the reaction mixture revealed the presence of a new compound with $R_{f}=0.45$ (hexane: diethyl ether 70:30) and the desired compound 161 was isolated in quantitative yield as a colourless oil (Scheme 2.16).

Yield 97-100\%
Scheme 2.16: O-alkylation reaction of phenol 162 and dioxolane 163
${ }^{1} \mathrm{H}$ NMR analysis of dioxolane 161 showed a multiplet at $\delta 7.37-7.25 \mathrm{ppm}$ that integrated for two protons and at $\delta 7.03-6.94 \mathrm{ppm}$ for three protons attributed to the five aromatic protons. A triplet at $\delta 5.15 \mathrm{ppm}(J=4.8 \mathrm{~Hz})$ which integrated for 1 H and attributed to the methine proton and a second triplet peak at $\delta 4.17 \mathrm{ppm}$ $(J=6.5 \mathrm{~Hz})$ and integrating for 2 protons attributed to the $\mathrm{OCH} \mathrm{H}_{2} \mathrm{CH}_{2}$ moiety. The use of COSY confirmed the resonance for the following methylene groups $\delta 2.25$ - 2.17 ppm attributed to $\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}$, and a multiplet at $\delta 4.08-4.00$ and 3.943.88 ppm attributed to $\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{O}$ respectively (Figure 2.7).

Figure 2.7: ${ }^{1} \mathrm{H}$ NMR spectrum of 161

The rationale for the synthesis of dioxane 165, 165a-c as well as the corresponding dioxolanes 161 and 161a-d was based upon the ease and mildness of the corresponding deprotection step. Also, as aldehydes are reactive species, both protected forms were used to avoid possible side reactions (Scheme 2.17).

Scheme 2.17: O-alkylation reaction of phenol 162 and dioxane 164

### 2.5.2 The Deprotection step-synthesis of aldehydes as prochiral precursors

The next part of the synthesis required the deprotection of the dioxolane 161 to reveal the desired aldehyde 160. This was obtained upon a simple acid hydrolysis of the dioxolane.

### 2.5.2.1 Acid hydrolysis of a dioxolane

Deprotection of the dioxolane ${ }^{107} 161$ and its derivatives were examined using a range of weak, mild and strong acids and oxidants in different solvent systems and at different temperatures and for a range of reaction times (Table 2.2). It was clear that the deprotection step was not as straight forward as forecast and the
best yield of aldehyde was obtained from the use of CAN ${ }^{108}$ using a method published by Maulide involving a dioxolane 161c to afford 160c. ${ }^{109}$

Scheme 2.18: Deprotection of dioxolanes to achieve the desired aldehydes

The deprotection reaction was carried out by dissolving 161c for instance, in a $1: 3$ solvent mixture of acetonitrile and water followed by the addition of a stoichiometric amount CAN. The reaction mixture was heated to $70^{\circ} \mathrm{C}$ for $5-10$ minutes during which the dark red colour changed to a yellowish solution. Tic showed the presence of a new compound with an $R_{f}=0.55$ (hexane: ether 70:30). The aldehyde 160c was isolated in a yield of $67 \%$ as a colourless oil. The corresponding ${ }^{1} \mathrm{H}$ NMR spectrum (Figure 2.8) showed a triplet at $\delta 9.9 \mathrm{ppm}$
$(J=1.2 \mathrm{~Hz})$ attributed to the aldehyde proton, a doublet at $\delta 7.66 \mathrm{ppm}(J=8.5$ $\mathrm{Hz})$ and $7.03 \mathrm{ppm}(J=8.5 \mathrm{~Hz})$ representing the 4 aromatic protons. A triplet resonating at $\delta 4.38 \mathrm{ppm}$ was characteristic of the $\mathrm{OCH}_{2} \mathrm{CH}_{2}$ methylene group and a doublet of triplets peak at $\delta 3.01 \mathrm{ppm}(2 \mathrm{H}, J=6.0,1.2 \mathrm{~Hz})$ belonged to $\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CHO}$.

Figure 2.8: ${ }^{1} \mathrm{H}$ NMR spectrum of aldehyde 160c

The synthesis of aldehyde 160, using CAN, was anticipated to be as straightforward as that for $\mathbf{1 6 0}$ c. The ${ }^{1} \mathrm{H}$ NMR spectrum seemed largely to be consistent with the desired aldehyde however the characteristic triplet at $\delta 9.9$ ppm, consistent with the aldehyde proton coupling to an adjacent methylene group, was absent. Detailed analysis of the NMR spectrum revealed only 4 aromatic protons suggesting that a cyclisation reaction had taken place to afford the corresponding chromanone 166 (Scheme 2.19). This was later confirmed by high resolution mass spectroscopy.

Scheme 2.19: Unexpected cyclisation of dioxolane to chromenone

Figure 2.9: ${ }^{1} \mathrm{H}$ NMR spectrum 166
This was an interesting and novel outcome and suggests that the following sequence of reactions had taken place (Scheme 2.20). Initially deprotection of dioxolane 161 occurred to afford the desired aldehyde 160 however the aromatic ring was sufficiently electron rich (nucleophilic), unlike aldehyde 160c, to cyclise to afford chromanol 167. In the presence of CAN this was then oxidised further to afford 166.

Scheme 2.20: Proposed route to chromenone 166

If this was a general outcome then other electron-rich dioxolanes such as 161a, 161b should also undergo the same series of oxidations to afford the corresponding chromanones. ${ }^{110}$ Inspection of the data in Table 2.2 confirms this to be the case thus exposure to dioxolanes 161, 161a-b to CAN for 5 minutes gave the corresponding aldehyde, in variable yields, however longer exposure times provided the chromanones 166, 166a, 166b in yields of 70-80 \% (Scheme 2.21).

Scheme 2.21: Cyclisation of the dioxolane to chromenone

Despite these interesting results it was still necessary to establish a reliable methodology for the synthesis and isolation of the key aldehydes. For the synthesis of the key aldehyde other methods were investigated.

### 2.5.2.2 Synthesis of aldehydes via deprotection of dioxolane as the corresponding dimethoxy-derivative

An alternative strategy involved accessing the aldehyde 160 via the dimethoxy ether $168^{107 b, 111}$ (Scheme 2.22) thus avoiding exposure of the sensitive aldehyde to CAN. This reaction was carried out by dissolving the dioxolane 161 in methanol and adding pTSA to the reaction mixture which was then heated to a reflux temperature for $7-8$ hours. The desired compound 168 was analysed by tic analysis $R_{f}=0.46$ (petroleum ether: diethyl ether $70: 30$ ), with a very low yield ( $8 \%$ ) and purification was very messy. In the second step the dimethoxy ether derivative 168 was added to a mixture of $\mathrm{THF} / \mathrm{H}_{2} \mathrm{O}(1: 1)$ in the presence of pTSA and stirred at room temperature for about 7 days. Tlc analysis of the reaction mixture showed the presence of a new compound $R_{f}=0.2$ (hexane: diethyl ether 70:30). The desired aldehyde 160 was then isolated with a yield of $12 \%$ partly attributed to its instability to purification by chromatography on silica gel. Given the low yield obtained, this methodology offered no advantage over the reaction with CAN.

161

168

160

Scheme 2.22: An alternative approach to the synthesis of aldehyde 160

### 2.5.2.3 Synthesis of the key aldehyde via oxidative cleavage of an epoxide

The third approach involved the oxidative cleavage of an epoxide which occurs in three steps (Scheme 2.23):
i) O-Alkylation ${ }^{106 b-e}$ of phenol 162 with bromide 169 to afford ether 170
ii) Epoxidation of $\mathbf{1 7 0}$ to afford epoxide 171
iii) Oxidative cleavage of 171 to aldehyde 160

Scheme 2.23: The synthesis of aldehyde 160 via an oxidative cleavage of an epoxide

The O-alkylation of phenol 162 was carried out to afford 170 as a colourless oil in $97 \%$ yield. The ${ }^{1} \mathrm{H}$ NMR spectrum (Figure 2.10) showed the presence of the $=\mathrm{CH}$ as a multiplet at $\delta 6.0-5.95 \mathrm{ppm}$ and the $=\mathrm{CH}_{2}$ as a multiplet at $\delta 5.22-5.14$ ppm.

Figure 2.10: ${ }^{1} \mathrm{H}$ NMR spectrum of alkene 170

Figure 2.11: ${ }^{13} \mathrm{C}$ DEPT spectrum of alkene 170

The corresponding ${ }^{13} \mathrm{C}$ DEPT NMR spectrum (Figure 2.11) showed the alkenyl $\mathrm{CH}_{2}$ resonating at $\delta 114.59 \mathrm{ppm}$ the $\mathrm{O}-\underline{\mathrm{C}}_{2}$ at $\delta 67 \mathrm{ppm}$ and the $\mathrm{O}-\mathrm{CH}_{2} \mathrm{CH}_{2}$ at $\delta$ 34 ppm . The epoxidation reaction of 170 took place by the exposure of the alkene $165 \mathrm{R}=\mathrm{H}$ to meta-chloroperoxybenzoic acid (mCPBA) to afford 2-(2phenoxyethyl) oxirane 171 in a yield of $87 \% .{ }^{1} \mathrm{H}$ NMR analysis showed two multiplets at $\delta 7.3$ and 6.9 ppm that integrated for 5 protons and attributable to the aromatic protons. In addition there were resonances at $\delta 4.08 \mathrm{ppm}$ of a triplet $(2 \mathrm{H}, \mathrm{t}, J=5.8 \mathrm{~Hz})$ that were attributed to $\mathrm{ArOCH}_{2}$, a doublet of doublets at $\delta 3.20$ ppm $(J=8.8,6.0 \mathrm{~Hz})$ and a doublet of doublets at $2.89 \mathrm{ppm}(J=8.8,6.0 \mathrm{~Hz})$ attributed to $\mathrm{CH}_{2}$ of the epoxide and a multiplet at $\delta 2.80-2.76 \mathrm{ppm}(1 \mathrm{H})$ attributed to $\mathrm{C} \underline{\mathrm{H}}$, a multiplet peak at $\delta 2.02-1.98 \mathrm{ppm}$ that integrated for 2 protons, attributed to $\mathrm{CH}_{2} \mathrm{CH}$ group.

The conversion of the epoxide to the aldehyde 160 using periodic acid in a mixture of THF: $\mathrm{H}_{2} \mathrm{O}$ (1:1) was achieved in a good yield (66\%). Aldehyde 160 was clean enough to use directly without further purification. In comparison to the use of CAN however this procedure was time consuming, more expensive and for reasons of atomic economy, the use of mCPBA was to be avoided. Furthermore there was still 20-30\% of the corresponding cyclised compound 166 formed as side product.

### 2.5.2.4 Synthesis of the aldehyde via oxidation of a $1^{\circ}$ alcohol

A fourth approach in the quest to obtain aldehyde 160 was from the Corey and Suggs oxidation of the corresponding primary alcohol $\mathbf{1 7 2}^{112}$ (Scheme 2.24). ${ }^{112 b, 113}$

Scheme 2.24: Synthesis of aldehyde via oxidation of a $1^{\circ}$ alcohol

The alcohol 172 was produced via a Williamson ether synthesis ${ }^{106 b-e}$ between phenol and 3-bromopropan-1-ol. The product of this reaction phenoxypropanol 172 was obtained with a yield of $84 \%$. GC-MS analysis gave a single peak with a molecular weight of $152 .{ }^{1} \mathrm{H}$ NMR analysis revealed the following characteristics of 172. A multiplet at $\delta \mathbf{7} \cdot 67-7.60 \mathrm{ppm}$ integrating for two protons and a multiplet at $\delta 7.32-7.28 \mathrm{ppm}$ attributed to 3 aromatic protons. At $\delta 4.46 \mathrm{ppm}$ there was a triplet $(J=6.5 \mathrm{~Hz})$ representing $\mathrm{OCH}_{2}$, a multiplet at $\delta 3.40-3.36 \mathrm{ppm}$ attributed to $\mathrm{CH}_{2} \mathrm{OH}$ and a broad singlet at $\delta 2.42 \mathrm{ppm}$ for the OH (Figure 2.12)

Figure 2.12: ${ }^{1}$ HNMR spectrum of alcohol 172

In the second step the alcohol 172 was dissolved in dry dichloromethane and a stoichiometric amount of pyridinium chlorochromate (PCC) was added to the solution as an oxidising agent. The colour of the solution changed to a red hue and it was left to stir for 5 hours and monitored by tlc. This showed a new spot consistent with the $\mathrm{R}_{\mathrm{f}}=0.55$ for the aldehyde 160. The reaction was quenched and the product isolated with a yield of $67 \%$. Although the overall yield for this sequence was good it was concluded that the method that used CAN to cleave the dioxolane directly to afford aldehyde 160 was the best way forward in the synthesis of the aldehyde.

### 2.5.3 The alkynylation reaction

An alkynylation reaction was carried out to synthesise the propargyl alcohol 159 on derivatives 159a-159c.

### 2.5.3.1 Synthesis of racemic propargyl alcohols

This was required in order to ascertain the retention time for each of the chiral propargyl alcohols produced and was carried via the Grignard reaction ${ }^{52,54}$ using commercially available organometallic-alkynyl reagents (Scheme 2.25).

Scheme 2.25: Synthesis of racemic propargyl alcohols

Due to the instability of aldehyde 160 the alkynylation reaction was carried out immediately upon isolation by dissolving the aldehyde in dry THF that had been cooled to $-78{ }^{\circ} \mathrm{C}$. The Grignard reagent was added drop-wise to the solution over a period of 15-20 minutes and the reaction mixture was left to stir for at least 1 hour. Tlc monitoring showed a new spot with an $R_{f}=0.14$ (hexane: diethyl ether $80: 20$ ). The product was then isolated and purified, by chromatography on silica, to afford (+/-) propargyl alcohol 159 as a colourless oil in $85 \%$ yield.

The corresponding ${ }^{1} \mathrm{H}$ NMR spectrum (Figure 2.13) showed the presence of peaks attributed to the aromatic ring at $\delta 7.32-7.26 \mathrm{ppm}$ which integrated for two protons and also at $\delta 6.96-6.89 \mathrm{ppm}$ integrating for a further 3 protons. Another multiplet at $\delta$ 4.74-4.69 attributed to the methine proton $\mathrm{CH}-\mathrm{OH}$. At $\delta 2.50 \mathrm{ppm}$ a doublet $(J=2.0 \mathrm{~Hz})$ represented the $\mathrm{C} \equiv \mathrm{CH}$ and another doublet slightly upfield at $\delta 2.42(J=5.8 \mathrm{~Hz})$ attributed to the OH moiety.

Figure 2.13: ${ }^{1}$ HNMR spectrum of propargyl alcohol 159

To complement this study it was decided to include the following library of propargyl alcohols to include 159, 159a-c as well as 174a and 174b derived from the propargylation of the readily available aldehyde 173 and propargyl alcohol 176 from the propargylation of aldehyde 175 (Scheme 2.26).

173
174a $R=P h$
174b R = PhMe

175
176

Scheme 2.26: Synthesis of racemic propargyl alcohols

Interestingly the ${ }^{1} \mathrm{H}$ NMR spectrum for 176 (Figure 2.14 ) showed a multiplet at $\delta$ $7.46-7.29 \mathrm{ppm}$ integrating for 10 aromatic protons. A multiplet centred at $\delta 4.64$ attributed to CHOH and a triplet at $\delta 2.87 \mathrm{ppm}(J=7.8 \mathrm{~Hz})$ attributed to the benzylic protons $\mathrm{PhCH}_{2}$. This assignment was confirmed from the corresponding COSY analysis which showed an interaction with an adjacent methylene group but not with the $-\underline{\mathrm{CH}}$ or $-\mathrm{O} \underline{H}$ peaks.

Figure 2.14: ${ }^{1} \mathrm{H}$ NMR spectrum of propargyl alcohol 176

### 2.5.4 Complexation reaction of the propargyl alcohol

Complexation of the propargyl alcohols 159, 159a-c, 174a/b and 176 with dicobalt octacarbonyl is the first step in the Nicholas reaction. This was
undertaken by dissolving the propargyl alcohol in dry DCM at ambient temperature followed by the addition of a stoichiometric amount of dicobalt octacarbonyl. As a representative example the dicobalt hexacarbonyl complex of propargyl alcohol 177 was obtained as a dark red oil in a quantitative yield (Scheme 2.27).

Scheme 2.27: Complexation of propargyl alcohol 159 using dicobalt octacarbonyl

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 7 7}$ (Figure 2.15) showed the characteristic features of these cobalt clusters i.e. broadened resonances that are devoid of any fine structure. An important feature of the alkyne clusters however is the downfield resonance attributed to $\mathrm{C} \equiv \mathrm{CH}$ proton. In $\mathbf{1 5 9}$ this is at $\delta 2.5 \mathrm{ppm}$ however in the complex 177 this was resonant at $\delta 6.0 \mathrm{ppm}$ consistent with the $\mathrm{sp}^{2}$ character of the carbon atoms associated with the complex.

Figure 2.15: ${ }^{1}$ H NMR spectrum of complex 177
A ready way to ascertain that the complexation step has been successful, apart from the red colour of the complex, is from the corresponding infrared spectrum. Here the carbonyl signals indicative of this metal carbonyl are clearly visible at $2012 \mathrm{~cm}^{-1}$ along with the disappearance of the alkyne signal another sign of this insertion (Figure 2.16).

Figure 2.16: IR spectrum of complex 177
The complexation of 159a-c was accomplished in quantitative yield to afford the coresponding complexes 177a-c.

Complexation of $174 \mathrm{a} / \mathrm{b}$ and 176 was also successfully accomplished using the same complexation procedure to afford the corresponding complexes 178a/b and 179 in quantitative yields (Scheme 2.28).

Scheme 2.28: Complexation of propargyl alcohol 174a/b and 176

### 2.5.5 The Nicholas reaction-cyclisation

With the range of complexes in hand the key intramolecular Nicholas cyclisation reaction in the presence of a Lewis acid at $0^{\circ} \mathrm{C}$ could now be attempted (Scheme 2.29).

Scheme 2.29: The Nicholas-cyclisation

Addition of the Lewis acid to 177 led to a very rapid cyclisation reaction as determined by a tlc taken within 5 minutes of the addition. This confirmed the presence of a new compound $R_{f}=0.86$ (hexane: diethyl ether $70: 30$ ) which was isolated and purified by removing most of the solvent and passing the crude product down a short silica column eluting with DCM. This gave the corresponding product 180 in $67 \%$ yield. ${ }^{1} \mathrm{H}$ NMR analysis revealed that the resonance attributed to the OH peak had disappeared and that the aromatic protons showed 4 protons (not 5) in 4 different chemical shifts each peak integrating for 1 proton (Figure 2.17). A broad singlet at $\delta 6.28 \mathrm{ppm}$ is attributed to $\mathrm{C} \equiv \mathrm{C} \underline{\mathrm{H}}$. The $\mathrm{O}-\mathrm{CH}_{2}$ protons $\mathrm{H}_{\mathrm{d}}$ and $\mathrm{H}_{\mathrm{e}}$ resonate individually at $\delta 4.44-4.40$ and 4.30-4.24 ppm and both show extensive spin-spin coupling with both the geminal proton $\left({ }^{2} J_{\mathrm{H}-\mathrm{H}}\right)$ and the 2 viscinal protons $\left({ }^{3} J_{\mathrm{H}-\mathrm{H}}\right)$ as shown in the NMR below. Proton $\mathrm{H}_{\mathrm{a}}$ is an apparent triplet is resonant at $\delta 4.2 \mathrm{ppm}(J=6.2 \mathrm{~Hz})$.

Figure 2.17: ${ }^{1} \mathrm{H}$ NMR spectrum of complex 180

The same cyclisation conditions were applied to propargyl alcohols 178a and 178b. These underwent successful Nicholas cyclisation reaction to afford the corresponding cyclic complexes 181a / 181b in yields of 77.6 and $71.2 \%$ when
exposed to the Lewis acid (Scheme 2.30). Lewis acid treatment of complex 179 gave the corresponding elimination product 183 rather than the cyclised product 182 (Scheme 2.31). Apparently the higher energy transition state required for the formation of a 5 -membered ring is too great thus facilitating a lower energy elimination reaction to occur instead.

Scheme 2.30: Nicholas cyclisation of 178a, 178b

182

183

Scheme 2.31: Elimination of propargyl alcohol

The corresponding ${ }^{1} \mathrm{H}$ NMR spectrum for the complex 183 (Figure 2.18) confirmed that an elimination reaction had taken place by showing 10 aromatic protons at $\delta 7.56-7.20 \mathrm{ppm}$ and resonances for the olefinic protons at $\delta 6.8$ ppm ( 1 H adjacent) to the complex motif) and a second at $\delta 6.4 \mathrm{ppm}$ ( 1 H adjacent to a methylene group).

Figure 2.18: ${ }^{1} H$ NMR spectrum of enyne complex of 183

### 2.5.6 The decomplexation step

The decomplexation step, to remove the dicobalt hexacarbonyl cluster, was carried out by addition of a methanolic solution of CAN to 183 at $0^{\circ} \mathrm{C}$. The complex was dissolved in methanol, cooled down to $0^{\circ} \mathrm{C}$ and a solution of CAN in methanol was added dropwise, with stirring, until the dark red solution changed to an orange/yellow colour (Scheme 2.32).

183
184
Scheme 2.32: Decomplexation step of 183

The yield of enyne 184 was $78 \%$ and the ${ }^{1} \mathrm{H}$ NMR spectrum for 184 showed resonances of 10 H at $\delta 7.2-7.5 \mathrm{ppm}$ characteristic of aromatic protons, a doublet of triplets at $\delta 6.4 \mathrm{ppm}(J=15.8,7.0 \mathrm{~Hz})$ for $\mathrm{CH}_{2} \mathrm{CH}=\mathrm{CH}$ and an upfield doublet of triplets at $\delta 5.7 \mathrm{ppm}(J=15.8,1.5 \mathrm{~Hz})$ for the second vinyl proton. The two methylene protons were resonant at $\delta 3.5 \mathrm{ppm}$ as a doublet of doublets $(J=$ $7.0,1.5 \mathrm{~Hz}$ ) (Figure 2.19 ).

Figure 2.19: ${ }^{1} H$ NMR spectrum of enyne 184

The decomplexation procedure was carried out upon the remaining cyclised complexes 180, 180a-c, 181a/b to afford the corresponding cyclised products 185, 185a-c, 186a/b. Tlc analyses of the reaction mixture confirmed the presence of a new compound $\mathrm{R}_{\mathrm{f}}=0.6$ (hexane: EtOAc 90:10): The new compound was isolated and purified by chromatography on silica gel to afford the desired chromane 185 in a yield of $97 \%$ (Scheme 2.33).

$180 \mathrm{R}=\mathrm{H}$
180a $R=M e$
180b R = Ph
180c $R=$ PhMe

$185 \mathrm{R}=\mathrm{H}$
185a $R=M e$
185b $R=P h$
185c $\mathrm{R}=\mathrm{PhMe}$

Scheme 2.33: Decomplexation reaction

The ${ }^{1} \mathrm{H}$ NMR spectrum for 185 (Figure 2.20) showed the alkyne proton resonated as a doublet $(J=2.5 \mathrm{~Hz})$ at $\delta 2.22 \mathrm{ppm}$. The $\mathrm{CH}_{2}$ protons $\alpha-$ to the ring oxygen resonated at $\delta 4.3 \mathrm{ppm}(1 \mathrm{H})$ and $4.2 \mathrm{ppm}(1 \mathrm{H})$. The benzylic proton resonated slightly upfield at $\delta 3.85 \mathrm{ppm}$ as a triplet of doublets $(J=6.0,2.5 \mathrm{~Hz})$ coupling to the adjacent methylene group as well as to the alkynyl proton.

Figure 2.20: ${ }^{1} \mathrm{H}$ NMR spectrum of chromene 185

The corresponding IR spectrum for 185 (Figure 2.21) clearly showed that the cobalt carbonyl peaks had disappeared at 2092.9, 2053.4 and $2022.1 \mathrm{~cm}^{-1}$ and showed the peak attributed to the alkyne moiety at $2054 / 2025 \mathrm{~cm}^{-1}$.

Figure 2.21: IR spectrum of chromene 185

The decomplexation step was also carried out on $181 \mathrm{a} / \mathrm{b}$ to provide the novel isochromane derivatives 186a and 186b in yields of 89 and $86 \%$ respectively (Scheme 2.34).

Scheme 2.34: Decomplexation of isochromene

### 2.5.7 Asymmetric synthesis chromenes

Having accomplished the Nicholas cyclisation reactions in a series of racemic syntheses the corresponding asymmetric synthesis were attempted. This required the synthesise of enantio-enriched propargyl alcohols.

### 2.5.7.1 Asymmetric propargylation reaction

The desired aldehyde 160 was obtained as previously described however the isomeric aldehyde 173 was commercially available. The method for effecting the asymmetric alkynylation reaction was the method described by Carreira ${ }^{9 a}$ and requires the use of $(+)$-N-methylephedrine which acts as a chiral catalyst and serves as a template during the reaction between the organometallic species and the aldehyde. (Scheme 2.35). The reaction was carried out using two different alkynes to afford the enantio-enriched propargyl alcohols $187 \mathrm{a} / \mathrm{b}$ from aldehyde 160 and 188a-c from aldehyde 173 in yields ranging from 75-98\% (Table 2.3)

187b R = PhMe

Scheme 2.35: Asymmetric alkynylation of 160 and 173

Table 2.3: Data for the Synthesis of Optically Active Propargyl Alcohols

| Propargyl <br> alcohol | $[\alpha]_{\mathrm{D}}$ | Yield \% | ee\% |
| :---: | :---: | :---: | :---: |
| 187 a | +17 | 76.2 | 50 |
| 187 b | +12 | 63.0 | 74 |
| 188 a | +15 | 98.1 | 80.6 |
| 188 b | -8 | 87.3 | 82.22 |
| 188 c | +10 | 81.5 | 77.12 |

The Carreira reaction was carried out on aldehydes, 160 and 173, by mixing (+)N -methylephedrine and zinc triflate, under a nitrogen atmosphere, with toluene and $E t_{3} \mathrm{~N}$. The resulting mixture was left to stir for 2 hours whereupon the alkyne was added. After stirring for a further 15 minutes the aldehyde was added and the reaction mixture was left to stir for about 7 days to effect the alkynylation reaction. TIc analysis for the synthesis of 187a, as an example, showed the presence of a new compound with an $\mathrm{R}_{\mathrm{f}}$ value of 0.4 (hexane: diethyl ether, 70:30). Isolation and purification of the product gave 187a in a yield of 76\% as a colourless oil. Chiral hplc was used in order to determine the enantiomeric excess for each asymmetric alkynylation reaction. For 187a the major enantiomer had a retention time $t_{\text {maj }}=7.49 \min (74.61 \%)$ and the $t_{\text {min }}$ was 14.38 minutes $(25.38 \%)$ giving an enantiomeric excess of $50 \%$. The enantiomeric excess of this asymmetric alkynylation reaction was modest. As all of the later asymmetric alkynylation reactions significantly improved enantiomeric excess it must be assumed that this initial data may be optimised. For example for $187 \mathrm{~b} \mathrm{t}_{\text {maj }}=$ 19.65 minute $(87 \%)$ and $t_{\text {min }}=24 \min (13.1 \%)$ giving an enantiomeric excess of 74\%.

The ${ }^{1} \mathrm{H}$ NMR of 187a (Figure 2.22) revealed the resonances for the aromatic protons as three multiplets at $\delta 7.46 \mathrm{ppm}(2 \mathrm{H}), 7.33 \mathrm{ppm}(6 \mathrm{H})$ and 6.87 ppm $(2 \mathrm{H}) \mathrm{ppm}$. Upfield at $\delta 4.99 \mathrm{ppm}$ there was a multiplet attributed to CHOH and two further multiplets at $\delta$ 4.29-4.39 and $4.15-4.27 \mathrm{ppm}$ attributed to $\mathrm{OCH}_{2}$. The hydroxyl proton appeared as a doublet $(J=5.8 \mathrm{~Hz})$ at $\delta 2.47 \mathrm{ppm}$.

187a

Figure 2.22: ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 8 7 a}$

Chiral hplc also was also used to determine enantiomeric excess for the isomeric propargyl alcohols 188a-c. For 188a major enantiomer had a retention time $\mathrm{t}_{\mathrm{maj}}=$ $28.99 \mathrm{~min}(90.3 \%)$ and the $\mathrm{t}_{\min }$ was $23.97 \mathrm{~min}(9.7 \%)$ providing an $\mathrm{ee} \%=80.6 \%$.

The ${ }^{1} \mathrm{H}$ NMR for 188a (Figure 2.23) revealed the resonance for CHOH at $\delta$ 4.80 ppm as a doublet of doublets of doublets $(J=7.49,5.04,3.58 \mathrm{~Hz}$ ), a doublet at $\delta 4.60(1 \mathrm{H})(J=12.0 \mathrm{~Hz})$ attributed to $\mathrm{PhCH}_{2} \mathrm{O}$ and a second doublet at $\delta$ $4.59 \mathrm{ppm}(1 \mathrm{H})(J=12.0 \mathrm{~Hz})$ attributed to the second benzylic proton. At $\delta 3.7-3.8$ ppm there is a multiplet attributed to $\mathrm{OCH}_{2} \mathrm{CH}$ and a doublet at $\delta 2.60 \mathrm{ppm}(1 \mathrm{H})$ $(J=5.0 \mathrm{~Hz})$ attributed to OH .

188a

Figure 2.23: ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 8 8 a}$

### 2.5.8 The complexation reaction

This step was carried out using the same procedure as that for the racemic propargyl alcohols to afford the enantio enriched dicobalt hexacarbonyl complexes 189a/b and also for the 190a-c (Scheme 2.36).

189a $R=P h$
189b R = PhMe

188a $\mathrm{R}=\mathrm{Ph}$
188b R = PhMe
188c $R=B n$

190b $R=$ PhMe
190c $\mathrm{R}=\mathrm{Bn}$
Scheme 2.36: Complexation of chiral phenoxy and benzyloxy propargyl alcohol

### 2.5.8.1 The Nicholas (cyclisation) reaction with an optically active substrate

The key factor in controlling the stereochemistry of the cyclisation reaction was temperature. As the two faces of the Nicholas cation are equally exposed to the nucleophile at temperatures above $0^{\circ} \mathrm{C}$ low temperatures $\left(-78^{\circ} \mathrm{C}\right)$ must be maintained. ${ }^{25,40}$ Then the rate of fluxional stabilisation is significantly reduced providing an opportunity for the nucleophile to attack onto one face only. The cyclisation reactions were carried out as previously described to afford the complexed chromanes 191a/b and the corresponding isochromane complexes 192a-c (Scheme 2.37)

Scheme 2.37: Asymmetric cyclisation of phenoxy and benzyloxy propargyl alcohol complexes

The reactions were monitored by tlc which showed the presence of a faster moving compound which for 191a the $\mathrm{R}_{\mathrm{f}}$ was 0.66 (hexane: diethyl ether $90: 10$ ). It was isolated in a yield of $63 \%$ after the purification step. ${ }^{1} \mathrm{H}$ NMR analysis showed the presence of 9 aromatic protons $(\mathrm{R}=\mathrm{Ph})$ at $\delta 7.35-7.22 \mathrm{ppm}(5 \mathrm{H})$, 7.1-7.00 ppm $(2 \mathrm{H}), 6.84 \mathrm{ppm}(1 \mathrm{H})$ and $6.73 \mathrm{ppm}(1 \mathrm{H})$. The presence of only 9 aromatic protons confirmed that cyclisation had taken place. The benzyl proton (CHC $\equiv \mathrm{CPh}$ ) appeared as a doublet of doublets at $\delta 4.51(1 \mathrm{H})(\mathrm{J}=6.0,6.0 \mathrm{~Hz}$, $\mathrm{CH})$, and there were multiplets at $\delta$ 4.3-4.2 $(1 \mathrm{H})$ and 4.2-4.1 ppm $(1 \mathrm{H})$ attributed to $\left(\mathrm{OCH}_{2} \mathrm{CH}_{2}\right)$. The adjacent protons to the benzyl proton $\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}\right)$ showed two multiplets at $2.50-2.32$ and $2.2-2.1 \mathrm{ppm}$ as they are diastereotopic protons and the OH peak was not apparent (Figure 2.24). The same procedure was repeated for compound 191b and 192b-c.

Figure 2.24: ${ }^{1} \mathrm{H}$ NMR spectrum of 191a

### 2.5.8.2 Decomplexation reaction and discussion

This was carried out as previously detailed. An important consideration was the possibility of partial racemisation occurring during the complexation, cyclisation and decomplexation reaction. Isolation of the corresponding chromanes 193a/b and isochromanes 194a-c were achieved in good yields ( $76-89 \%$ ) (Scheme 2.38).

Scheme 2.38: Decomplexation of optically active chromenes and iso-chromenes

Hplc analysis of chromane 193a showed $\mathrm{t}_{\text {major }}=8.58$ minutes $(72.61 \%)$ and $\mathrm{t}_{\text {minor }}$ $=16.73 \mathrm{~min}(27.39 \%)$ for $193 \mathrm{~b} \mathrm{t}_{\text {major }}=13.60 \mathrm{~min}(85.26 \%)$ and $\mathrm{t}_{\text {minor }} 16.96$ minutes ( $14.74 \%$ ). From these data the corrected enantiomeric excess ${ }^{49}$ for the syntheses of 193a and 193b may be determined. The corrected enantiomeric excess is determined as the enantiomeric excess of the products 193a/b divided by the enantiomeric excess of the cyclisation precursors $187 \mathrm{a} / \mathrm{b}$ expressed as a percentage. For the syntheses of chromane 193a the corrected enantiomeric excess was $45 / 50 \times 100=90 \%$ and for the synthesis of 193b the corrected enantiomeric excess was $71 / 74 \times 100=96 \%$.

Consideration of the Nicholas cyclisation of propargyl alcohol 187a, from molecular mechanical modelling experiments, suggests that the pyran ring may
be formed as a twisted chair in which the alkynyl functional group is appropriately orientated so as to minimise the non-aromatic ring energy. ${ }^{114}$ This is achieved by the alkyne group adopting a pseudo-equatorial position. This tends to reduce steric interactions such as 1,3-diaxial interactions between the alkyne and protons $\mathrm{H}_{3 \mathrm{a}}{ }_{83 \mathrm{e}}$ as well as ensuring that the the cobalt-stabilised cation is aligned in close proximity to the adjacent nucleophilic aromatic ring (Figure 2.25).

Figure 2.25: $3 D$ structure of chromene 193a
${ }^{1} \mathrm{H}$ NMR analysis of chromane 193a is shown (Figure 2.26) and confirmed the structure by showing 9 aromatic protons at $\delta 6.6-7.5 \mathrm{ppm}$ and two doublet od doubltes of doubltes at $\delta 4.44(1 \mathrm{H})$ and $4.26 \mathrm{ppm}(1 \mathrm{H})$ with $(J=11.0,7.5,3.0$ Hz ), attributed to $\mathrm{OCH}_{2}$. Interestingly the benzyl proton was shifted to $\delta 4.10 \mathrm{ppm}$ as a triplet ( $J=6.2 \mathrm{~Hz}$ ), a multiplet at $\delta 2.26-2.04 \mathrm{ppm}$ was attributed to the $\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}$ protons.

Figure 2.26: ${ }^{1} \mathrm{H}$ NMR spectrum of chromene 193a

The corresponding ${ }^{13} \mathrm{C}$ NMR spectrum (Figure 2.27) showed resonances for the aromatic carbon atoms attached to oxygen at $\delta 153.93 \mathrm{ppm}$ and the remaining 9 aromatic carbons at $\delta 131.74,129.86,128.45,128.31,128.04,123.43,121.88$, $120.64,117.07 \mathrm{ppm}$. Peaks at $\delta 91.31$ and 82.21 ppm may be attributed to ( $\mathrm{C} \equiv \mathrm{C}$ ) and at $\delta 64.44 \mathrm{ppm}$ attributed to $\left(\mathrm{PHOCH}_{2} \mathrm{CH}_{2} \mathrm{CH}\right)$. Further peaks at $\delta$ 29.16 and 28.13 ppm may be attributed $\left(\mathrm{OCH}_{2} \mathrm{CH}_{2} \underline{\mathrm{CH}}\right)$.

Figure 2.27: ${ }^{13} \mathrm{C}$ NMR spectrum of chromene 193a
An associated ${ }^{13} \mathrm{C}$ DEPT experiment of 193a (Figure 2.28 ) showed two $\mathrm{CH}_{2}$ carbons at $\delta 64.44$ and 29.16 ppm and one CH carbon at $\delta 28.13 \mathrm{ppm}$. The resonances attributed to the alkynyl carbon atoms between $\delta 80-92 \mathrm{ppm}$ have disappeared.

Figure 2.28: ${ }^{13} \mathrm{C}$ DEPT of the chromene 193a

The data associated with chromanes 193a, b and for isochromanes 194a-c are included in (Table 2.4). Analyses of these data reveal that the Nicholas cyclisation reactions took place with high levels of enantioselectivity. It confirms that having secured the propargyl alcohol enantioselectively the subsequent cycle of complexation, Nicholas cyclisation and decomplexation occurs with very low to zero levels of racemisation. This suggests that the low experimental temperatures required to secure this level of selectivity is attributed to a combination of slow rates of diffusion of the "leaving group" from the complex in combination with minimal fluxional rotation of the cobalt stabilised cation that allows the nucleophile to attack one face only.

Table 2.4: HPLC Data and Specific Rotation for the 193 And 194

| Chromenea/isochromenes | $[\alpha]_{\mathbf{D}}$ | Yield \% | ee\% | Corrected <br> ee\% |
| :---: | :---: | :---: | :---: | :---: |
| 193a | -38 | 76.2 | 45.2 | 90.5 |
| 193 b | -10 | 79.0 | 70.5 | 95.3 |
| 194 a | +13 | 79.0 | 77.3 | 95.9 |
| 194 b | -21 | 89.3 | 81.6 | 99.2 |
| 194 c | -9 | 88.6 | 76.1 | 98.6 |
| $194 \mathbf{d}^{\text {1 }}$ | -13 | 85.0 | 77.3 | 90.5 |

${ }^{\top}$ For comparison purposes e.g hplc retention times etc it was also carried out the reaction using (-)-N-methylephedrine

In conclution these enantiospecific reactions were successfully achieved with high enantioselectivities. The next development in this area was to consider the Nicholas cyclisation in which the stabilised cation 195 is quenched not by an aromatic ring but by the comparatively electron rich double bond. Note that the initial stereogenic centre, formed from the Nicholas cyclisation, then results in the formation of an adjacent second stereocenter in the second cation 196 (Scheme 2.39).

Scheme 2.39: Nicholas cyclisation via cation 195

### 2.6 The synthesis of a benzopyran

### 2.6.1 Retrosynthesis

Different approaches for accessing the Nicholas cyclisation precursor 198 are shown in the following retrosynthesis (Scheme 2.40). It is based upon a strategy that was used to synthesise benzopyrans for biological screening as
hypertensive reagents. ${ }^{115}$ The two approaches shown, either via the aldehyde 197 or the propargyl alcohol 200 , both begin with salicylaldehyde 199 which is commercially available.

Scheme 2.40: Two routes to propargyl alcohol 198

### 2.6.2 Racemic approach to the synthesis of a benzopyran

Initially 198 was formed by the O-alkylation of 199 , to afford 197 , followed by the alkynylation reaction. Thus O-alkylation of salicylaldehyde 199 to afford 197 was carried out using a similar procedure to that described in section 2.5.1. Tlc analysis of the reaction mixture showed that a new compound was present with an $R_{f}$ value of 0.5 (petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether, $80: 20$ ). The desired compound 197 was isolated in a quantitative yield $99-100 \%$. ${ }^{1} \mathrm{H}$ NMR spectroscopy confirmed the structure of 197 by showing the aldehyde resonance $(1 \mathrm{H})$ at $\delta 10.39 \mathrm{ppm}$ as a singlet. A doublet of doublets at $\delta 5.46 \mathrm{ppm}(J=6.71$, 1.09 Hz ) atributed to $\mathrm{C} \underline{H}=\mathrm{C}$, and two singlets at $\delta 1.79 \mathrm{ppm}$ and 1.71 ppm attributed to the two vinyl methyl groups.

The alkynylation reaction of 197 was carried out using the analogous procedure to that described (Section 2.5.3) using three different Grignard reagents to afford desired propargyl alcohols 198a-c in excellent yield of $81-93 \%$. The ${ }^{1} \mathrm{H}$ NMR
spectrum for 198a showed that the resonance attributed to the aldehyde CHO group had disappeared and a new doublet at $\delta 3.30 \mathrm{ppm}(J=6.2 \mathrm{~Hz})$ was seen attributed to OH .

### 2.6.3 Complexation, Nicholas cyclisation and decomplexation

The complexation with dicobalt hexacarbonyl was carried out using the same procedure as previously described (Section 2.5.4) to afford the cobalt complexes 201a-c as dark red oils in yield 91-96\% (Scheme 2.41)

Scheme 2.41: Complexation of 198a-c using dicobaltoctacarbonyl

The Nicholas cyclisation was carried out by exposing each of the complexes 201a-c, maintained at a temperature of $0{ }^{\circ} \mathrm{C}$, to the Lewis acid $\mathrm{BF}_{3} \mathrm{OEt}_{2}$. From the previous investigations ${ }^{22 a}$ it was noted that the probable outcome of the cyclisation reaction would be the formation of the fluorinated complex 203a-c (Scheme 2.42).

Scheme 2.42: Cyclisation of propargyl alcohol 201a-c

This arises as a result of the halogenation of the incipient second cation, such as 196, that is formed as a result of the cyclisation of 202a-c. It is probable that the fluorine atom is derived from the dissociation of the Lewis acid during the cyclisation sequence. This was a very useful outcome and enabled the use of ${ }^{19} \mathrm{~F}$ NMR spectroscopy to be used in the analyses of the products.

The decomplexation step was carried out using CAN as described earlier (Section 2.5.6) to afford the fluorinated benzopyrans 204a-c in yields of $66.4 \%$, $70 \%$ and $73 \%$. It was noted, for the first time, that prolonged exposure of the benzopyran 204a to CAN led to a further oxidation reaction to afford the novel chromene 205 in a yield of $71.4 \%$. The reaction could, however, be tuned to favour 204a-c only by careful monitoring of the progress of the reaction by tlc analysis and therefore reducing the time that the decomplexed product was exposed to CAN (Scheme 2.43).

203a $R=P h$
203b R = PhMe 203cR= PhOMe

$$
\begin{aligned}
& \text { 204a } R=\text { Ph } \\
& \text { 204b } R=P h M e \\
& 204 c R=\text { PhOMe } \\
& 66-73 \%
\end{aligned}
$$

Scheme 2.43: Decomplexation of flouro-benzopyran derivatives

Spectroscopic analyses of the benzopyrans 204a-c were undertaken and the ${ }^{1} \mathrm{H}$ NMR of 204a is shown (Figure 2.29). At $\delta \mathbf{7 . 5 2 - 6 . 8 5 ~ p p m ~ t h e r e ~ a r e ~ a ~ s e r i e s ~ o f ~}$ resonances attributed to 9 aromatic protons. At $\delta 4.5 \mathrm{ppm}$ is an apparent doublet of triplets intergrating for $1 \mathrm{H}\left(\mathrm{OCH}_{2}\right)(J=11.7,3.3 \mathrm{~Hz})$ and a second resonance at $\delta 4.18 \mathrm{ppm}(1 \mathrm{H})$ as a doublet of doublets $(J=11.7,6.0 \mathrm{~Hz})$ for $\mathrm{OCH}_{2}, 4.12$ ppm ( $1 \mathrm{H}, \mathrm{d}(J=5.6 \mathrm{~Hz})$, attributed to $\mathrm{PhC} \underline{H C} \equiv \mathrm{C})$ and a multiplet at $\delta 2.58-2.63$ (1H) attributed to $\left.\mathrm{CH}_{2} \mathrm{CHCF}\right)$, $\delta 1.55 \mathrm{ppm}\left(3 \mathrm{H}, \mathrm{d},\left(J=20.1 \mathrm{~Hz}, \mathrm{CCH}_{3} \mathrm{~F}\right), \delta 1.48\right.$ ppm ( $3 \mathrm{H}, \mathrm{d}\left(J=20.1 \mathrm{~Hz}\right.$ ), $\left.\mathrm{CCH}_{3} \mathrm{~F}\right)$.

Figure 2.29: ${ }^{1} \mathrm{H}$ NMR spectrum of flouro-benzopyran 204a

It was previously demonstrated that the Nicholas cyclisation reactions are completely diastereoselective and in keeping with the previous investigations the coupling constant $J$ for the benzylic proton at $\delta 4.12 \mathrm{ppm}$ of 4.2 Hz is suggestive of a cis-relative stereochemistry. Further evidence to confirm that the cyclisation reactions are completely diastereoselective was obtained from the corresponding ${ }^{19} \mathrm{~F}$ NMR spectrum which shows only one resonance $\delta$-135.25 ppm, corresponding to the two cis- benzopyran 204a which are related as enantiomers and thus have identical physical properties in an achiral environment (Figure 2.30).

Figure 2.30: ${ }^{19}$ F NMR spectrum of flouro-benzopyran 204a

The corresponding ${ }^{13} \mathrm{C}$ spectrum showed resonances for 10 aromatic carbons at $\delta 153.97,131.59,130.18,128.28,128.26,128.08,123.27,121.89,121.27$, 116.94 ppm consistent with the structure 204a. In addition there were further resonances at $\delta 96.64 \mathrm{ppm}\left(\underline{C} F, d, J_{F}=168.5 \mathrm{~Hz}\right.$ ) and $\delta 91.92,82.58 \mathrm{ppm}$ attributed to $(\mathrm{C} \equiv \mathrm{C})$, peaks at $\delta 64.53\left(\mathrm{~d},{ }^{4} \mathrm{~J}_{\mathrm{C}-\mathrm{F}}=9.9 \mathrm{~Hz}\right), 47.57\left(\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{C}-\mathrm{F}}=22.5\right.$ $\mathrm{Hz}), 28.96\left(\mathrm{~d},{ }^{4} \mathrm{~J}_{\mathrm{C}-\mathrm{F}}=5.6 \mathrm{~Hz}\right), 26.16\left(\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{C}-\mathrm{F}}=24.5 \mathrm{~Hz}\right), 25.19\left(\mathrm{~d},{ }^{3} \mathrm{~J}_{\mathrm{C}-\mathrm{F}}=24.5\right)$ (Figure 2.31).

Figure 2.31: ${ }^{13} \mathrm{C}$ NMR spectrum of flouro-benzopyran 204a

From this study it was concluded that the synthesis of the ( $+/-$ ) benzopyrans 204a-c was successfully accomplished and that the key cyclisation reaction took place with complete control over the diastereoselectivity of the contiguous chiral centres. The next phase of this study was an attempt at the corresponding asymmetric variant.

### 2.6.4 Asymmetric synthesis of benzopyrans

The asymmetric alkynylation of aldehyde 197 was carried out with three different Grignard reagents using the Carreira methodology to afford the desired optically active propargyl alcohols 206a-c in yield of $72.7 \%, 83.8 \%$, and $92.5 \%$ respectively. The spectral data for these compounds was similar to those synthesised under racemic conditions however they were analysed by polarimetry and chiral HPLC (Scheme 2.44).

Scheme 2.44: Asymmetric synthesis of propargyl alcohols 206a-c

The specific rotation for 206a was measured as $[\mathrm{a}]_{\mathrm{D}}^{23}=+10^{\circ}$ ( $\mathrm{c}=1 \%$ ethanol) and the melting point was $52^{\circ} \mathrm{C}$. Chiral hplc analysis for 206a gave $\mathrm{t}_{\text {minor }}=16.6$ $\min (2.5 \%)$ and $\mathrm{t}_{\text {major }}=12 \mathrm{~min}(97.5 \%)$ which provides an enantiomeric excess of 95 \%. Data for the same analyses for 206b and 206c are provided in Table 2.5.

Table 2.5: Data for Chiral Propargyl Alcohols 206a-c

| Propargyl <br> alcohol | $[\mathbf{a}]_{\mathbf{D}}^{23}$ | $\mathbf{t}_{\text {minor }}$ | $\mathbf{t}_{\text {major }}$ | ee\% |
| :---: | :---: | :---: | :---: | :---: |
| 206 a | +10 | 2.5 | 97.5 | 95 |
| 206 b | -13 | 2 | 98.0 | 96 |
| 206 c | +11 | 1.5 | 98.5 | 97 |

Having secured the syntheses of the important cyclisation precursors the next step involved the key Nicholas cyclisation of the corresponding dicobalt hexacarbonyl complexes 207a-c (formed in yields of $97.5 \%, 97.8 \%$, $95.4 \%$ respectively) (Scheme 2.45 ). The reactions were performed as previously described, although the cyclisation was conducted at $-78^{\circ} \mathrm{C}$ as these were chiral substrates, to afford the corresponding benzopyrans 209a-c.

Scheme 2.45: Asymmetric synthesis of flouro-benzopyran derivatives 209a-c

The spectroscopic data for these benzopyrans was similar to those previously described however polarimetry and chiral hplc data was collected and shown in (Table 2.6).

Table 2.6: Data for Optically Active Benzopyrans 209a-c

| Benzopyran | $[\mathbf{a}]_{\mathbf{D}}^{23}$ | $\mathbf{t}_{\text {minor }}$ | $\mathbf{t}_{\text {major }}$ | ee\% | corrected |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | ee |
| 209 a | -9 | 3 | 97 | 94 | 98 |
| $209 b$ | -11 | 5.7 | 94.3 | 88.6 | 92 |
| 209 c | +15 | 6.5 | 93.5 | 87 | 90 |

At the present time the absolute configuration of the stereocentres in 209a-c was not confirmed, the future aims however include the synthesis of a solid crystalline derivative in order to obtain an X-Ray structure. The Nicholas reaction occurs by attack of the nucleophile from the rear side of the leaving group i.e. the other face away from the leaving group. At $-78^{\circ} \mathrm{C}$ this leads to a stereospecific cyclisation, as the synthesis chromanes such as 193a-b and 195a-c. In these examples, however, the stereospecific nature of the cyclisation step also ensures that no scrambling can occur as the contiguous chiral centre is sequentially generated and therefore affording (cis-diastereoselectivity the $J=4.0 \mathrm{~Hz}$ value of the benzylic proton ( $\mathrm{CH} \mathrm{C} \equiv \mathrm{C}$ ) confirmed the cis configuration. The corrected enantiomeric excess of the three benzopyrans 209a-c of $98 \%, 92 \%$ and $90 \%$ were excellent, confirming the success of the original methodology and suggesting that the aim to effect an asymmetric Nicholas Reaction was achieved. This initially provides the propargylic centre asymmetrically and then controls the formation of the second stereocentre. In the next phase of this study it was explored the use of the chiral pool compound citronellal as a suitable chiral precursor.

A comparison of the chiral hplc data for 209a with the corresponding products. from the racemic reaction are shown in Figure 2.33. These data showed that the major diastereoisomer has a retention time $t_{R}$ at 13.35 minutes and the minor at 9.83 minutes. The corresponding ${ }^{19} \mathrm{~F}$ NMR spectrum (Figure 2.32) reveals the presence of one resonance only for the enantiomeric mixture that resonates at $\delta$ 135 ppm:

Figure 2.32: ${ }^{19}$ F NMR spectrum of chiral flouro-benzopyran 209a

opticaly acitve 209a

racemic mixture 204a

Figure 2.33: hplc of the 209a and 204a

### 2.7 Chiral pool

An asymmetric alkynylation was one of the key reactions to achieve the corresponding propargyl alcohol from aldehyde as a precursor in the Nicholas reactions. (S)-Citronellal 210 is a chiral aldehyde which it has previously demonstrated undergoes alkynylation with minimal stereocontrol from the $\beta$ asymmetric centre. The corresponding propargyl alcohols are formed as a 48:52 mixture of diastereoisomers. To improve upon this diastereoselectivity, a Carreira asymmetric alkynylation on 210 was performed to afford the diastereo enriched propargyl alcohol 211 (Scheme 2.46).

Scheme 2.46: Asymmetric alkynylation of the citronellal 210

The alkynylation reaction was monitored by tlc which showed the presence of a faster moving compound with an $\mathrm{R}_{\mathrm{f}}=0.90$ (petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ : diethyl ether, 70:30). In order to prevent any form of diastereomeric resolution no attempt was made to purify the crude product mixture, by column chromatography on silica, instead it was decided to carry out the spectroscopic analysis on the crude product. This was isolated in a yield of $88 \%$, and the optical rotation for 211 was measured as $[a]_{D}^{23}=+11^{\circ}\left(\mathrm{c}=1 \%\right.$ ethanol). From the ${ }^{1} \mathrm{H}$ NMR spectrum it was possible able to ascertain a diasteromeric excess of $57 \%$ a considerable improvement upon the alkynylation reaction without a chiral ligand. ${ }^{1} \mathrm{H}$ NMR analysis showed the presence of 5 aromatic protons at $\delta 7.5-7.2 \mathrm{ppm}$ $(5 \mathrm{H})$, at $\delta 5.0 \mathrm{ppm}$ a broad triplet peak $(J=6.3 \mathrm{~Hz})$ attributed to CHOH , a triplet peak $(J=5.5 \mathrm{~Hz})$ at $4.55 \mathrm{ppm}(1 \mathrm{H})$ attributed to $=\mathrm{CH})$, a singlet peak at $\delta 2.3$ $\mathrm{ppm}(1 \mathrm{H})$ attributed to $\mathrm{O} \underline{\mathrm{H}}$, multiplet peaks at $2.0-1.25 \mathrm{ppm}(4 \mathrm{H})$ attributed to two $\mathrm{CH}_{2}$, two singlets at $\delta 1.6 \mathrm{ppm}$ and 1.5 ppm attributed to each $=\mathrm{CCH}_{3}$, a multiplet at $\delta 1.45-1.08 \mathrm{ppm}(4 \mathrm{H})$ attributed to $\mathrm{CHCH}_{3}$ and $\left.\mathrm{CH}_{2}\right)$; a doublet at 0.92 and $0.76 \mathrm{ppm}(3 \mathrm{H})(J=6.5 \mathrm{~Hz})$ attributed to $\mathrm{CH}_{3}$, major $=78 \%$, minor $=21 \%$.
In order to improve upon the diastereoselectivity of the propargylation reaction it was considered the synthesis of a derivative of citronellal 210 based upon 212 in which the chiral centres are contiguous (Scheme 2.47).

Scheme 2.47: Synthesis of novel diastereoselective propargyl alcohol 213

In this example chiral auxiliary technology could be employed to stereoselectively install the $R$ group $\alpha$ - to the carbonyl where it may be able to control the subsequent alkynylation reaction (Scheme 2.48).

The preparation of aldehyde 212 is shown in Scheme 2.48 which involves alkylation of the acylated chiral auxiliary 214 to achieve 215. The synthesis of aldehyde 212 is then obtained from the hydrolysis of the auxiliary from 215.

212
Scheme 2.48: Synthesis of novel chiral aldehyde 212

It was envisaged that complexation of the propargyl alcohol 213 and Nicholas cyclisation would afford the corresponding trisubstituted cyclohexane 216 with possible stereocontrol over the three contiguous chiral centres (Scheme 2.49)

Scheme 2.49: Synthesis of novel trisubstituted cyclohexane 216

### 2.8 Chiral Auxiliary

As a preparation it was investigated the chemistry of a small range of Evans chiral auxiliaries 217a-d in an acylation reaction with an acid chloride to afford 218a-d (Scheme 2.50)

Scheme 2.50: Acylation of Evans chiral auxiliary

Table 2.7: Data for Chiral Auxiliary 218a-d

| Oxazolidine | product | $[\alpha]_{D}$ | ee or de\% | Yield\% |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $+75^{98-99}$ | $98$ | 99 |
|  |  | + $+73^{116}$ | 78.5 | $98$ |
|  |  | $+47^{117}$ | 97.6 | 99 |
|  |  | $-40^{94 \mathrm{c}}$ | 95 | 98.5 |

Analysis of 218c revealed that as $\mathrm{H}_{\mathrm{a}}, \mathrm{H}_{\mathrm{b}}$ (see below) are diastereotopic the ${ }^{1} \mathrm{H}$ NMR showed that they resonate at different chemical shifts. The Newman projection shows $H_{a}$ is close with $H_{c}$ and interacts with both $H_{b}$ and $H_{c}$ likewise $H_{b}$ is interaction with $\mathrm{H}_{\mathrm{a}}$ and $\mathrm{H}_{\mathrm{c}}$. (Figure 2.34)

Figure 2.34: Newman projection of 218 c

The ${ }^{1} \mathrm{H}$ NMR spectrum showed $H_{\mathrm{a}}$ as a dd $\delta 3.25-3.21$ ppm ( $1 \mathrm{H}, \mathrm{dd}, J=13.4$, $3.2 \mathrm{~Hz})$ and $H_{\mathrm{b}}$ at $\delta 2.79-2.67 \mathrm{ppm}(1 \mathrm{H}, \mathrm{dd}, J=13.4,9.6 \mathrm{~Hz})$. In addition $H_{c}$ was noted $\delta 4.6 \mathrm{ppm}(1 \mathrm{H}, \mathrm{m})$.

### 2.8.1 Model study of the alkylation of benzyl oxazolidinone

As the benzyloxazolidinone 218c had the highest enantiomeric excess this was selected to carry out the next step the alkenylation reaction. Thus lithium chelation of 218c, from exposure to butyllithium, and alkylation with (i) benzyl bromide or (ii) 3-bromopropene provided the corresponding derivatives $219 \mathrm{a} / \mathrm{b}$ in excellent yields $(78,87 \%)$ and with optical data $\left([a]_{D}^{23}=+123^{\circ}\right.$ for 219 a and $[a]_{D}^{23}$ $=+75^{\circ}$ for 219 b ) that was consistent with literature values (Scheme 2.51).

Scheme 2.51: Evans alkylation to oxazolidinone 218c

Data for the derivatives is summarised in Table 2.8

Table 2.8: Data for Chiral Auxiliary Derivatives 218

| $\mathrm{R}-\mathrm{Br}$ | product | $[\alpha]_{D}$ | $\begin{aligned} & \mathrm{de} \\ & \% \\ & \hline \end{aligned}$ | Yield \% |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $+123^{946,98}$ | 82 | 86 |
|  |  | $+75^{118}$ | 78 | 84 |

The next phase involved the cleavage of the chiral auxiliary, however unfortunately due to limitations in time this stage of the project was not completed.

### 2.9 Achievements and Conclusions

This project involved a number of approaches to an asymmetric Nicholas reaction. The most successful approach involved the use of a chiral propargyl alcohol which acts to control the subsequent bond forming reaction/s during the key Nicholas reaction. Despite the, known, fluxional behaviour of the stabilised cation the chiral "memory" of the optically pure propargyl alcohol is retained at low temperatures. This enabled us to successfully synthesis two series of oxygen heterocycles that were enantio enriched.

This study involved chiral pool synthesis, although very likely to provide a further set of optically active carbocycles was thwarted by a lack of time to carry out the study.

### 2.10 Future Direction

A number of further investigates are suggested by the results of this work. Therefore it would be interesting to investigate the following aspects in more detail:

1- Find an appropriate chiral catalyst for asymmetric 1,4-conjugate addition of cyclohexane with desired haloalkane. As it was described in section 2.4.2, chiral catalyst system was applied to achieve an asymmetric 1,4-conjugate addition by using Josiphos 82 and Taniaphos 84 which was abortive (Scheme 2.8). Therefore using other chiral catalyst mentioned in Table 1.3 would be valuable work to do in future.

2 - As the asymmetric synthesis of the chromene and isochromene and also benzopyran was succeed. It would be favourable to carry out the same method to synthesis optically pure thiochromene and also quinolone derivatives.

2 H -thiochromene

Fluoro-2H-thiochromene

Tetrahydroquinoline

Fluoro-tetrahydroquinoline

3- Asymmetric alkynylation of the Citronelall to accomplish a stereospecific Nicholas reaction by using chiral auxiliary. As the Citronelall is a chiral aldehyde an asymmetric alkynylation to provide corresponding optically active alcohol would be applied. An asymmetric inramoecular Nicholas reaction could accomplish the cyclisation reaction.

## 3 Experimental

### 3.1 General procedures

Starting materials were provided from Sigma-Aldrich and Fischer Scientific unless otherwise stated. Except for the decomplexation reaction all other reactions were carried out under an inert atmosphere of $\mathrm{N}_{2}$. The glassware was oven dried at $150^{\circ} \mathrm{C}$ overnight prior to use. Dry solvents such as toluene, THF, diethyl ether, DCM and DMF were purchased from Sigma-Aldrich.

Organic extractions were carried out using laboratory grade solvents and the organic extracts were dried over anhydrous magnesium sulphate, filtered and concentrated by evaporation of the solvents under reduced pressure using a rotary evaporator. Analytical thin layer chromatography, TLC, was carried out using silica gel with fluorescent indicator ( 60 F254, $200 \mu \mathrm{~m}$ thick). They were visualised using either UVGL-58 multiband UV - 254/365 nm mineralight lamp or/ and by heating after immersion in aqueous potassium permanganate. Reactions were monitored by TLC using a solvent system with various ratios of hexane, diethyl ether, light petroleum spirit (bp $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ), chloroform and DCM. Column chromatography was carried out using silica gel 60 (particle size 35-70 $\mu \mathrm{m}$ ) purchased from Fischer Scientific. The mobile phase systems were mixtures of laboratory grade solvents mentioned above for the TLC monitoring.

### 3.2 Instrumentation

NMR data were acquired using a Bruker $400 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right)$ spectrometer using Topspin version 2.1 control and processing software. Chemical shifts are reported using the chemical shift of the solvent residual proton(s) as internal standard. The operating frequencies are 400 MHz and 100 MHz for proton and carbon and fluorine nuclei respectively. Infra Red (IR) spectrophotometer using was a Perkin-Elmer Paragon 100 series FT-IR spectrophotometer using spectumversion 5.3.1 control and processing software. The spectra were obtained after placing a drop of the sample on a NaCl plate and allowing the solvent to evaporate. Low resolution mass spectra were recorded on an Agilent Technologies Quiadrupole Mass Spectrometer under Electron Impact (EI) conditions at an ionising potential of 70 eV . Also in a Hewlett Packard GC-MS instrument, HP 5890 II (GC) with capillary column and BP X5 (MS), using a direct insertion probe with a probe temperature controller from Scientific instrument. Services, Inc, Ringose, NJ, USA on a version 1200L Quadrupole MS controlled using Varian Saturn GC/MS system controle version 6.41. Accurate mass analyses were performed and reported on a MAT95 or MAT900 instrument under various conditions (EI, CI, FAB, and ES) by the EPSRC National Mass Spectrometry Service Centre (Swansea). Enantiomeric excesses were measured by HPLC (Perkin Elmer Series 225), (Chiralcel OD-H column). Detector of HPLC was Waters 996 photodiode array diode detector. UV spectra were extracted and obtained directly from HPLC analysis via diode array detector. $[\alpha]_{D}^{T}$ Values were recorded using "Optically Activity LTD, AA-10 Automatic polarimeter" where T was the temperature at the time of measuring.

### 3.3 Conventions

The following conventions have been adopted for quoting physical data.
$R_{f}$ data (Solvent system)
ee (given in percentage)
de (given in percentage)
$t_{R}$ data (major), data (minor). The retation time $\left(T_{R}\right)$ is coated in minutes.
$[\alpha]_{D}^{T}$ data ${ }^{\circ}(\mathrm{c}=$ data, solvent $)$
mp data ${ }^{\circ} \mathrm{C}$
$\boldsymbol{v}_{\text {max }}(\mathrm{NaCl}) / \mathrm{cm}^{-1}$ are data refers to major bands in wavenumbers.
$\delta_{H}\left(\mathrm{MHz}\right.$; solvent) ${ }^{1} \mathrm{H}$ NMR data where $\mathrm{s}=$ singlet, $\mathrm{br} s=$ broad singlet, d , $=$ doublet, $\mathrm{dd}=$ doublet of doublets, $\mathrm{ddd}=$ doublet of doublets of doublets, $\mathrm{dt}=$ doublet of triplets, $t=$ triplet, $t d=$ triplet of doublets, $m=$ multiplet and the coupling constant $J$ are given in Hertz $(\mathrm{Hz})$. H-Ar represents aromatic proton.

ठc (MHz; solvent) ${ }^{13} \mathrm{C}$ NMR data where $\mathrm{C}=$ quaternary carbon, $\mathrm{CH}=$ methine, $\mathrm{CH}_{2}=$ methylene, $\mathrm{CH}_{3}=$ methyl and the coupling constant with fluorine atom $J_{c-F}$ are given in Hz . In all cases, Ar represents aromatic carbon.

LRMS (condition) $(\mathrm{m} / \mathrm{z}) \mathrm{M}^{+}$data (where $\mathrm{M}^{+}$refers to the parent ion and El could be different condition).

HRMS (condition) $[\mathrm{M}]^{+}$observed data for (molecular formula) theoretical data

### 3.4 Experimental procedures

### 3.4.1 Model study

The synthesis of hexacarbonyl [propioaldehyde diethyl acetal] dicobalt (45)

Dicobalt octacarbonyl ( $1.71 \mathrm{~g}, 5 \mathrm{mmol}$ ) was transferred, under a nitrogen atmosphere, to a dry pre-weighed 100 mL round bottom flask. Anhydrous dichloromethane ( 50 mL ) was introduced via a syringe, followed by 3,3-diethoxy-1-propyne ( $0.64 \mathrm{~g}, 5 \mathrm{mmol}$ ). The solution was stirred for an hour until CO evolution was no longer visible, tlc analysis after 1 hour showed the loss of the starting material and the presence of a new compound with an $R_{f}=0.4$ (hexane: diethyl ether $80: 20$ ) whereupon the solvent was removed in vacuo. The compound was purified by chromatography on silica gel ${ }^{119}$ ( $75: 25$ petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether) to afford the desired product as a dark red oil ( $2.0 \mathrm{~g}, 99 \%$ ).

IR $v_{\text {max }}$ (neat)/cm ${ }^{-1}: 2980.2$ (w); 2872.1 (w); 2090.0 (s); 2023.8(s); 1655.1, 953.3, 841.5, 730.0

 $\left(\underline{\mathrm{C}} \mathrm{H}(\mathrm{OEt})_{2}\right) ; 70.91\left(\underline{\mathrm{C}}_{2}\right) ; 63.04\left(\underline{\mathrm{C}}_{2}\right) ; 15.00\left(2 \times \underline{\mathrm{C}} \mathrm{H}_{3}\right)$.

The synthesis of trimethylsily 3-(4-methylpent-3-en-1-yl) cyclohex-1-en-1olate (46)

3-Methylpentyl-3-enylmagnesium bromide was synthesisd in situ by dropwise addition of 2-bromo-2-methyl-2-pentene ( $3.04 \mathrm{~g}, 18.64 \mathrm{mmol}$ ) to a flame dried 250 mL flask containing magnesium turnings ( $0.48 \mathrm{~g}, 20 \mathrm{mmol}$ ) in anhydrous THF ( 10 mL ) and a crystal of iodine and heated to a reflux temperature. The dropwise addition was done at such as to maintain a vigorous reaction. Upon completion the reaction was heated to a reflux temperature for half an hour whereby the solution was colourless with small amounts of residual solid material.
The reaction mixture was cooled to an ambient temperature whereupon THF (10 mL ) was added. The mixture was then cooled to $-78{ }^{\circ} \mathrm{C}$, and $\mathrm{CuBr} . \mathrm{Me}_{2} \mathrm{~S}(0.14 \mathrm{~g}$, 0.67 mmol ) was added and stirred for 10-15 minutes after this time trimethylsilyl chloride ( $4 \mathrm{~g}, 37.4 \mathrm{mmol}$ ) and 2-cyclohexen-1-one $73(1.28 \mathrm{~g}, 13.35 \mathrm{mmol})$ were added and left to stir. TIc analysis after 1 hour showed the loss of the starting material and the presence of a new compound with an $R_{f}=0.88$ ( $80: 20$, hexane: ethyl acetate). Triethylamine ( $2.75 \mathrm{~g}, 27: 18 \mathrm{mmol}$ ) was added, the solution was filtered through a plug of ceilite. The solvent was removed in vacuo. The aqueous phase was extracted with hexane ( $3 \times 20 \mathrm{~mL}$ ) and the organic layer was dried over anhydrous magnesium sulphate, filtered and concentrated in vacuo. The crude product was isolated and purified by chromatography on silica (80:20 hexane: ethyl acetate) to afford the title product 46 as a colourless oil ( $3.0 \mathrm{~g}, 89$ $\%$ ). HRMS (EI): [M ${ }^{+}$] observed 252.4680 for $\mathrm{C}_{15} \mathrm{H}_{28}$ SiO theoretical 252.4677

To a stirred suspension of $\mathrm{CuBr}^{2} \mathrm{SMe}_{2}(2.14 \mathrm{~g}, 10.4 \mathrm{mmol}, 1 \mathrm{eq})$ in anhydrous THF ( 10 mL ) maintained under an atmosphere of nitrogen at $-78^{\circ} \mathrm{C}$, was added a solution of cyclohex-2-en-1-one ( $1.0 \mathrm{~g}, 10.4 \mathrm{mmol}, 1 \mathrm{eq}$ ) in THF ( 5 mL ) and left to stir for 10 minutes. To the stirred solution was added, dropwise, ethylmagnesium bromide dissolved in THF ( 7 mL of a 3 M solution in diethyl ether, $20.8 \mathrm{mmol}, 2$ eq). After stirring for a further 15 minutes trimethylisilyl chloride ( $2.3 \mathrm{~g}, 21 \mathrm{mmol}, 2 \mathrm{eq}$ ) was added to the solution and the mixture was left to stir for a further 1 hour at $-78^{\circ} \mathrm{C}$. After this time the acetone ice bath was removed and the solution was allowed to warm to an ambient termperature, with stirring, for about 3 hours. During this time the solution darkened. After 1 hour Tlc analysis (petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether, 8:2) showed the loss of the starting material and the presence of a new compound ( $R_{f}=0.81$ ). Triethylamine ( $2.12 \mathrm{~g}, 21 \mathrm{mmol}, 2 \mathrm{eq}$ ) was added to the mixture followed by water ( 20 mL ). The solution was filtered through a plug of celite and the solvent, THF, was removed in vacuo. The aqueous phase was extracted with hexane ( 3 x 20 mL ) and the organic layer was dried over anhydrous magnesium sulphate, filtered and concentrated in vacuo to afford the title compound 46a as yellow oil ( $1.8 \mathrm{~g}, 90 \%$ ). This was considered sufficiently pure to use in the next step without further purification.

The synthesis of hexacarbonyl [1-ethoxy-2-propynal)-3- (4-methylpent-3enyl) cyclohexan-1-one] dicobalt (47)

Cobalt cluster 45 ( $2.80 \mathrm{~g}, 7.84 \mathrm{mmol}$ ) and O-silylenol ether 46 ( $2.00 \mathrm{~g}, 7.84$ mmol ) were mixed in a 3 -necked round bottomed flask containing dry DCM (20 mL ). The resulting solution was cooled to $-78{ }^{\circ} \mathrm{C}$, with continuous stirring, whereupon boron trifluoride diethyl etherate ( $11.18 \mathrm{~g}, 70.8 \mathrm{mmol}$ ) was added. The reaction was stirred for 3 hours at $-78^{\circ} \mathrm{C}$, before allowing it to reach an ambient temperature. Tlc analysis with an ( $\mathrm{R}_{\mathrm{f}}=0.6$ ) (petroleum ether ( $60^{\circ} \mathrm{C}-80$ ${ }^{\circ} \mathrm{C}$ ): diethyl ether, $3: 1$ ), after 1 hour showed the loss of the starting material and the presence of a new compound in relation to the cobalt cluster. The reaction mixture was quenched, by the addition of a saturated sodium bicarbonate solution ( 20 mL ) and the aqueous layer was partitioned, washed with DCM (3 X 20 mL ) and the combined organic layers were dried over anhydrous magnesium sulphate, fitered and the solvent removed in vacuo to give the desired product as a dark red oil, ( $3.36 \mathrm{~g}, 85 \%$ ). This was decomplexed. Please see page 108 for data.

The synthesis of 3,3-dimethyl-3,3a,4,5,5a,6;7,8,9a,9b-decahydro-9H-cyclopenta[a]naphthalen-9-one (144)

The cobalt complex cluster 47 ( $1.6 \mathrm{~g}, 3 \mathrm{mmol}$ ); was dissolved in DCM $(20 \mathrm{~mL})$; and the reaction was cooled to $-78{ }^{\circ} \mathrm{C}$ whereupon tetrafluoroboric acid $(1.04 \mathrm{~g}$, 6.50 mmol ) was added via a syringe. The reaction mixture was left to stir for 3 hours. TIc analysis with an ( $\mathrm{R}_{\mathrm{f}}=0.6$ ) ( $8: 2$ hexane: ethyl acetate), after 3 hours showed the loss of the starting material and the presence of a new faster moving compound. The solvent, $D C M$, was removed in vacuo and dicobalt hexacarbonyl complex ( $1 \mathrm{~g}, 1.9 \mathrm{mmol}$ ) was dissolved in methanol ( 30 mL ) and the reaction was cooled to $0^{\circ} \mathrm{C}$. Ceric ammonium nitrate ( $4.7 \mathrm{~g}, 8.5 \mathrm{mmol}$ ); dissolved in methanol $(20 \mathrm{~mL})$; was added portiowise, with continuous stirring, until the evolution of CO ceased and the orange colour of CAN persisted. TIc analysis after 15 minutes showed the loss of the starting material and the presence of a new compound with an $R_{f}=0.7$, (hexane: diethyl ether $70: 30$ ) The reaction mixture was then poured into a separating funnel containing diethyl ether ( 50 mL ) and water ( 50 mL ). The layers were separated and the aqueous layer was extracted with diethyl ether ( $3 \times 30 \mathrm{~mL}$ ). The combined organic layers were washed with sodium hydrogen carbonate ( $3 \times 30 \mathrm{~mL}$ ) and brine ( $3 \times 30 \mathrm{~mL}$ ) solutions and dried over anhydrous $\mathrm{MgSO}_{4}$. The reaction mixture was filtered and the solvent removed in vacuo, to yield a yellow oil. Purification on silica gel eluted with ( $80: 20$ petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether) was carried out to yield the title product 144 as a yellow oil ( $0.15 \mathrm{~g}, 35 \%$ );

The synthesis of (3R) - (+) - 3-ethyl-1-[(trimethylsilyl) oxy]-1-cyclohexene (150)

A mixture of CuBr. $\mathrm{SMe}_{2}$ ( $0.06 \mathrm{~g}, 0.3 \mathrm{mmol}$ ) and Taniaphos ${ }^{74}(23 \mathrm{mg}, 0.36 \mathrm{mmol})$ was added to a flame dried schlenk tube and dissolved in diethyl ether ( 3 mL ). This was left to stir at an ambient temperature for 30 minutes under an atmosphere of nitrogen, whereupon the cyclohex-2-en-1-one ( $0.57 \mathrm{~g}, 6 \mathrm{mmol}$ ) was added. Temperature reduced to $-78^{\circ} \mathrm{C}$, stirring continued for a further 10 minutes followed by the dropwise addition of ethylmagnesium bromide ( 4 mL of the 3 M solution in diethyl ether, 12 mmol$)$. After about 15 minutes $\mathrm{Si}\left(\mathrm{CH}_{3}\right)_{3} \mathrm{Cl}$ ( $1.3 \mathrm{~g}, 12 \mathrm{mmol}, 2 \mathrm{eq}$ ) was added to the solution and the mixture was left to stir for a further 1 hour at $-78^{\circ} \mathrm{C}$. After this time the acetone ice bath was removed and the solution was allowed to warm to an ambient temperature, with stirring, for about 3 hours. During this time the solution darkened. After 3 hours tlc analysis with an $\left(R_{f}=0.80\right)$ (hexane: diethyl ether, $8: 2$ ) showed the loss of the starting material and the presence of a new compound. Triethylamine ( $1.2 \mathrm{~g}, 12 \mathrm{mmol}$ ) was added to the mixture followed by water $(20 \mathrm{~mL})$. The solution was filtered through a plug of ceilite and the solvent, THF, was removed in vacuo. The aqueous phase was extracted with diethyl ether ( $3 \times 20 \mathrm{~mL}$ ) and the organic layer was dried over anhydrous magnesium sulphate, filtered and concentrated in vacuo to afford the title compound 150 as yellow oil ( $0.73 \mathrm{~g}, 98 \%$ ).
The ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}, \operatorname{IR}$ and LRMS spectra were identical with the data obtained for compound 46a. The following additional data was obtained. [a]D $=+11^{\circ}(\mathrm{c}=$ $2.5 \%$, chloroform); (ee\% $=70 \%$ ) (enantiomeric exces in lit. is for enantiomer of the $\left.150-10.3, \mathrm{c}=2.9 \%, \mathrm{CHCl}_{3}\right)^{103}$

The synthesis of hexacarbonyl [9-ethynyl-3, 4, 4a, 9, 9a, 10-hexahydro anthracen-1 $(2 \mathrm{H})$-one] dicobalt (153)

The cobalt complex 154 ( $0.6 \mathrm{~g}, 1.13 \mathrm{mmol}$ ); was dissolved in DCM ( 20 mL ) and the reaction was cooled to $-78{ }^{\circ} \mathrm{C}$ whereupon tetrafluoroboric acid ( $0.36 \mathrm{~g}, 3$ mmol ) was added via a syringe. The reaction mixture was left to stir for 40 minutes and a Tlc analysis with an $\left(\mathrm{R}_{\mathrm{f}}=0.7\right)\left(7: 3\right.$ petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ : diethyl ether), after 40 minutes showed the loss of the starting material and the presence of a new compound. The reaction mixture was quenched with a saturated solution of sodium hydrogen carbonate ( 30 mL ). The organic layer was separated, using a separating funnel, and the aqueous layer was extracted with DCM ( $3 \times 10 \mathrm{~mL}$ ). The combined organic layers were washed with brine $(1 \times 20$ mL ) and then dried over anhydrous $\mathrm{MgSO}_{4}$. The solid was then filtered and the solvent removed in vacuo and purified on silica gel eluted with ( $80: 20$, hexane: diethyl ether) to gave title compound as a dark red/brown oil ( $0: 22 \mathrm{~g}, 40 \%$ ).

## The synthesis of hexacarbonyl [3-benzyl-2- (1-hydroxyprop-2-yn-1-yl)

 cyclohexanone] dicobalt (154)

The cobalt cluster $45(2.0 \mathrm{~g}, 5.9 \mathrm{mmol})$ and the O-silylenol ether $46 \mathrm{e}(0.6 \mathrm{~g}, 2$ mmol ) were mixed in a 3-necked round bottomed flask containing dry DCM (20 mL ). The resulting solution was then cooled to $-78^{\circ} \mathrm{C}$ with continuous stirring whereupon boron trifluoride diethyl etherate $\left(\mathrm{BF}_{3} . \mathrm{OEt}_{2}\right)(0.2 \mathrm{~g}, 1 \mathrm{mmol})$ was added. The reaction was stirred for 3 hours at $-78^{\circ} \mathrm{C}$, before allowing it to reach an ambient temperature. Tlc analysis with an $\left(R_{f}=0.51\right)$ (light petroleum $\left(60^{\circ} \mathrm{C}\right.$ $80^{\circ} \mathrm{C}$ ): diethyl ether, $7: 3$ ), after 1 hour showed the loss of the starting material and the presence of a slower moving new compound. The reaction mixture was quenched by the addition of a saturated sodium bicarbonate solution ( 20 mL ) and the aqueous layer was partitioned and washed with DCM $(3 \times 20 \mathrm{~mL})$. The combined organic layers were dried over anhydrous $\mathrm{MgSO}_{4}$, filtered and the solvent removed in vacuo to give the title compound 154 as a dark red oil, $(0.8 \mathrm{~g}$, $65 \%$ ).

Method 1: The 2-(2-phenoxyethyl)-1, 3-dioxolane 161 ( $1.0 \mathrm{~g}, 5.15 \mathrm{mmol}, 1 \mathrm{eq}$ ) was placed in round bottom flask and ceric ammonium nitrate (CAN) ( 1.76 g , $5.15 \mathrm{mmol}, 1 \mathrm{eq}$ ) was added. The solvent mixture of water and acetonitrile ( 30 mL ) in 1:2 ratios was added and the mixture was warmed to $70^{\circ} \mathrm{C}$ and stirred for 5 minutes. After 5 minutes tlc analysis showed the loss of the starting material and the presence of a new compound with an $R_{f}=0.5$ (hexane: diethyl ether, $70: 30$ ). The reaction mixture was quenched by the addition of water ( 30 mL ) and extracted with DCM ( $3 \times 30 \mathrm{~mL}$ ). The organic phase was then washed with saturated solution of $\mathrm{NaHCO}_{3}(3 \times 30 \mathrm{~mL})$ and brine $(5 \times 30 \mathrm{~mL})$. The organic phase was dried over anhydrous magnesium sulphate, filtered and solvent was removed under vacuum. Light yellow oil was extracted from organic layer and was purified by column chromatography on silica gel using a mixture of hexane and diethyl ether in ratio of $60: 40$ as a mobile phase. Aldehyde 160 was not stable therefore it was synthesised in situ for each propargyl alcohol derivatives. The best yield for the title compound was ( $0.2-0.5 \mathrm{~g}, 60-70 \%$ )

Method 2: The epoxide 171 ( $1.26 \mathrm{~g}, 7.7 \mathrm{mmol}$ ) was placed in a 250 mL round bottom flask and a solvent system consisting of THF: $\mathrm{H}_{2} \mathrm{O}(1: 1)(15 \mathrm{~mL})$ was added followed by periodic acid $\left(\mathrm{H}_{5} \mathrm{IO}_{6}\right)(1.75 \mathrm{~g}, 7.7 \mathrm{mmol})$. The solution was stirred for 5 h and tlc monitoring showed a new compound with an $\mathrm{R}_{\mathrm{f}}=0.5$ (hexane: diethyl ether, 70:30), as aldehyde 160 was not stable on silica gel purification, it was used as crude ( $0.76 \mathrm{~g}, 66 \%$ ).

Method 3: The alcohol $172(2 \mathrm{~g}, 13.15 \mathrm{mmol})$ was placed in a dry 250 mL round bottom flask, under nitrogen, at an ambient temperature. Pyridinium chlorochromate (PCC) ( $2.84 \mathrm{~g}, 13.15 \mathrm{mmol}$ ) in anhydrous DCM ( 15 mL ) was added. The mixture was stirred for $6-8$ hours. Tlc analysis showed a new spot with an $\mathrm{R}_{\mathrm{f}}=0.5$ (hexane: diethyl ether, $70: 30$ ), ( $1 \mathrm{~g}, 50 \%$ ).

The synthesis of 4- (3-oxopropoxy) benzonitrile (160c)

The same method was employed as described for the synthesis of the 160 with the following quantities; 4-[2- (1,3-dioxolan-2-yl) ethoxy] benzonitrile 161 c ( 1 g , $5.71 \mathrm{mmol})$ and CAN ( $1.76 \mathrm{~g}, 5.15 \mathrm{mmol}$ ) mixed in the same solvent mixture. After 30 minutes tlc analysis showed the loss of the starting material and the presence of a new compound with an $\mathrm{R}_{\mathrm{f}}=0.55$ (hexan: diethyl ether, 70:30). Purification on silica gel eluted (hexane: diethyl ether, 70:30) was carried out to afford title compound as a colourless oil ( $0.71 \mathrm{~g}, 88 \%$ )
Method 2: The same method was employed as described in method 2 for the synthesis of the 160a with the following quantities; epoxide 171 b ( $1.95 \mathrm{~g}, 10.6$ mmol ) followed with the mixture of solvent THF and water in the ratio of 1:1 (20 mL ) was added subsequently periodic acid $\left(\mathrm{H}_{5} \mathrm{IO}_{6}\right)(2.41 \mathrm{~g}, 10.6 \mathrm{mmol})$ was poured in the solution mixture and stirred for 5 hours. After 5 hours tlc analysis showed the loss of the starting material and the presence of a new compound with an $R_{f}=0.55$ (hexane: diethyl ether, 70:30) compound sufficiently was pure ( $1.2 \mathrm{~g}, 66.7 \%$ ).

The synthesis of 2- (2-phenoxyethyl)-1, 3-dioxolane (161)

To a mixture of phenol ( $2.5 \mathrm{~g}, 26.6 \mathrm{mmol}, 1 \mathrm{eq}$ ); potassium carbonate ( 14.70 g , $106.4 \mathrm{mmol}, 4 \mathrm{eq}$ ) and potassium iodide ( $0.44 \mathrm{~g}, 2.66 \mathrm{mmol}$ ). To this mixture was added DMF ( 30 mL ) and 2- (2-bromoethyl)-1, 3-dioxolane ( $4.8 \mathrm{~g}, 26.6 \mathrm{mmol}$ ) under nitrogen atmosphere. The mixture was stirred at an ambient temperature for 3 hours. After 3 hours tlc analysis with an ( $\mathrm{R}_{\mathrm{f}}=0.45$ ) (hexane: diethyl ether, $70: 30$ ) showed the loss of the starting material and the presence of a new compound. The reaction was quenched by the addition of water ( 30 mL ) and placed in a separating funnel. The mixture was then extracted with diethyl ether $(3 \times 25 \mathrm{~mL})$. The organic layers were combined and washed successively with a saturated solution of lithium chloride ( $4 \times 25 \mathrm{~mL}$ ) to remove any residual DMF. The combined organic layers were then dried over anhydrous magnesium sulphate, filtered and the solvent removed in vacuo to afford the title compound ( $5.1 \mathrm{~g}, 98 \%$ ) as colourless oil. This was sufficiently pure to use in the next stage without further purification.

### 3.4.2 Novel racemic Nicholas cyclisations

## The synthesis of hexacarbonyl 4-ethynyl-3, 4-dihydro-2H-chromene dicobalt (180)

Hexacarbonyl propargyl alcohol dicobalt $177(0.155 \mathrm{~g}, 0.335 \mathrm{mmol}, 1 \mathrm{eq})$ was placed in a dry round bottom flask $(100 \mathrm{~mL})$ in dry DCM $(10 \mathrm{~mL})$ under $\mathrm{N}_{2}$. The solution then cooled in ice to $0^{\circ} \mathrm{C}$ whereupon $\mathrm{BF}_{3} . \mathrm{Et}_{2} \mathrm{O}(0.1 \mathrm{~g}, 0.67 \mathrm{mmol}, 2 \mathrm{eq})$ was added drop-wise over 5 minutes. After 5 minutes tlc analysis showed the loss of the starting material and the presence of a faster moving new compound with an $R_{f}=0.86$ (hexane: diethyl ether, 70:30). The reaction was quenched by the adition of distilled water ( 20 mL ) and extract with DCM ( $3 \times 20 \mathrm{~mL}$ ). The organic layer was separated from the aqueous layer by a separating funnel and dried over anhydrous magnesium sulphate. The magnesium sulphate was filtered and the DCM was removed in vacuo. The dark red compound was purified by chromatography using the solvent system petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ and ether $(90: 10)$ and the title compound was isolated as a dark red oil ( $0.1 \mathrm{~g}, 67 \%$ ). IR $V_{\max }$ (neat)/cm ${ }^{-1}$ : 2925.28 (w); 2854.64 (m); 2092.89 (m); 2053.40 (s); 2022.14 (s); 1487.68 (m); 1452.46 (s); 1223.52 (s); 1071.16 (s); 752.62 (s).

The synthesis of hexacarbonyl 4-[ (4-methylphenyl) ethynyl]-3, 4-dihydro-1H-isochromene dicobalt (181b)

The same method was employed as described for the synthesis of the 180 with the following quantities hexacarbonyl propargyl alcohol dicobalt $178 \mathrm{~b}(1.97 \mathrm{~g}, 3.6$ $\mathrm{mmol}) ; \mathrm{BF}_{3} . \mathrm{Et}_{2} \mathrm{O}(1.2 \mathrm{~g}, 7.2 \mathrm{mmol})$ mixed in dry DCM ( 20 mL ) after 10 mintues tlc analysis showed the loss of the starting material and the presence of a faster moving new compound with an $R_{f}=0.7$ (hexane: diethyl ether, 80:20). Reaction was quenched with distil water and extract with DCM ( $3 \times 20 \mathrm{~mL}$ ). Organic layer was separated from aqueous by a separating funnel and dried over magnesium sulphate, filtered, and DCM was removed via vacuum. Dark red oil compound was purified by by chromatography on silica using a solvent system petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ and ether $(90: 10)$; dark red oil compound was isolated (1.36 g, 71.2\%).

### 3.4.3 Novel chiral Nicholas cyclisations

The synthesis of (3R)-5-phenoxy-1-phenylpent-1-yn-3-ol (187a)

A 100 mL flask was charged with $\mathrm{Zn}(\mathrm{OTf})_{2}(0.67 \mathrm{~g}, 1.84 \mathrm{mmol})$ and (+)-(1S, 2R-N-methylephedrine ( $0.36 \mathrm{~g}, 2 \mathrm{mmol}$ ) and p urged with $\mathrm{N}_{2}$, stirred for 15 min whereupon toluene $(20 \mathrm{~mL})$ and triethylamine ( $\left.\mathrm{Et}_{3} \mathrm{~N}\right)(0.4 \mathrm{~g}, 4.0 \mathrm{mmol})$ was added via a syringe. The resulting mixture was left to stir for 2 hours before the phenylacetylene ( $0.5 \mathrm{~g}, 5.0 \mathrm{mmol}$ ) was added by syringe in one portion. After 15 minutes of stirring aldehyde $160(0.25 \mathrm{~g}, 1.67$ mmol ) was added in one portion. After completion 7 days, tlc checking showed finishing the starting material and presence of a new compound with an $R_{f}=0.26$ (petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether, $70: 30$ ). Purification by chromatography on silica gel eluted with (hexane: ethyl acetate, 85:15) gave the title product as a colourless oil ( $0.32 \mathrm{~g}, 76.2 \%$ ). ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ and IR and LRMS spectra are identical with the data for compound 159b. The following additional data was obtained. $[\alpha]_{D}=+17^{\circ}$ ( $\mathrm{c}=1 \%$ diethyl ether); ee $\%=50.45$, HPLC (Chiralcel OD-H, $10 \%$ i-PrOH-hexane, 254 nm ): $t_{R}=7.49$ major ( $74.61 \%$ ), $t_{R}=$ 14.38 minor ( $25.38 \%$ ).

HRMS (EI): $\left[\mathrm{M}+\mathrm{NH}_{4}\right]$ observed 270.1491 for $\left(\mathrm{C}_{17} \mathrm{H}_{16} \mathrm{O}_{2} \mathrm{NH}_{4}\right)$ theoretical 270.1489

## The synthesis of (3R)-1- (4-methylphenyl)-5-phenoxypent-1-yn-3-ol (187b)

The same method was employed as described for the synthesis of compound 187a, $\mathrm{Zn}(\mathrm{OTf})_{2}(1.20 \mathrm{~g}, 3.3 \mathrm{mmol})$ and $(+)-(1 \mathrm{~S}, 2 \mathrm{R})$-Nmethylephedrine $(0.65 \mathrm{~g}$, 3.6 mmol ) and purged with $\mathrm{N}_{2}$ in ambient temperature, stirred for 15 min whereupon toluene ( 10 mL ) and triethylamine ( $\mathrm{Et}_{3} \mathrm{~N}$ ) ( $0.75 \mathrm{~g}, 7.4 \mathrm{mmol}$ ) was added via a syringe. After 2 hours, 1 -ethynyl-4-methylbenzene ( $1.044 \mathrm{~g}, 9.0$ mmol ) was added by syringe in one portion. After 15 minutes of stirring aldehyde $160(0.45 \mathrm{~g}, 3.0 \mathrm{mmol})$ was added it took $7-10$ days to complete the reaction and tlc monitoring showed less amount of the remained and revealed a new spot in $R_{f}$ $=0.3$ (hexane: diethyl ether, 70:30). Purification by chromatography on silica gel eluted with (hexane: ethyl acetate, 80:20) gave the title product as a colourless oil $(0.19 \mathrm{~g}, 63.0 \%) .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ and $\operatorname{IR}$ and LRMS spectra are identical with the data for compound 159b. The following additional data was obtained. $[a]_{D}^{23}=$ $+12^{\circ}$ (c $=1 \%$, diethyl ether), ee\% $=73.8 \%$, HPLC (Chiralcel OD-H, $10 \%$ i-PrOHhexane, 254 nm ): $t_{R}=19.65$ major ( $87 \%$ ), $t_{R}=23.98$ minor ( $13 \%$ ).

The synthesis of 1-[2-[ (3-methylbut-2-en-1-yl) oxy] phenyl]-3-phenylprop-2-yn-1-ol (198a)

Method 1: Aldehyde 197 ( $1.6 \mathrm{~g}, 8.2 \mathrm{mmol}, 1 \mathrm{eq}$ ) was placed in round-bottom flask containing dry THF ( 15 mL ) and maintained under an atmosphere of nitrogen gas. The reaction temperature was reduced to $-10^{\circ} \mathrm{C}$ and phenylethynyl magnesiumbromide solution ( 9 mL of the 1 M solution in hexane, 9 mmol ) was added drop wise over a period of 20 minutes. Stirring at $-10^{\circ} \mathrm{C}$ was continued for about 1 hour and then allowed to reach an ambient temperature. After 3 hours tlc monitoring showed the loss of the starting material and the presence of a new compound with an $\mathrm{R}_{\mathrm{f}}=0.47$ (petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether $60: 40$ ). The reaction mixture was quenched by the addition of $\mathrm{HCl}(30 \mathrm{~mL}$ of a 2 M solution) and the mixture extracted with diethyl ether ( $3 \times 30 \mathrm{~mL}$ ). The combined organic solvent was dried over magnesium sulphate, filtered and the solvent removedin vacuo. Purification on silica gel eluted with hexane/diethyl ether (80:20) was carried out to afford title compound as a colourless oil ( $2.0 \mathrm{~g}, 81.3 \%$ ). Method 2: Propargyl alcohol 200a ( $1.0 \mathrm{~g}, 4.5 \mathrm{mmol}$ ) was placed in a 250 mL flame dried flask under at an atmosphere of nitrogen at an ambient temperature. Anhydrous DMF ( 20 mL ) was added followed by potassium carbonate $(2.5 \mathrm{~g}$, $18.0 \mathrm{mmol})$ and potassium iodide $(0.075 \mathrm{~g}, 0.45 \mathrm{mmol})$ and they were left to stir for in before 4-bromo-2methyl-2-butene ( $0.67 \mathrm{~g}, 4.5 \mathrm{mmol}$ ) was added. The reaction mixture was left to stir for 3 hours after that tlc monitoring showed the loss of the starting material and the presence of a new compound with $R_{f}=0.49$ (petroleum ether $\left(60^{\circ} \mathrm{C}-40^{\circ} \mathrm{C}\right.$ ): diethyl ether $60: 40$ ). The colourless oil was isolated which was sufficiently pure for use in the next stage ( $0.98 \mathrm{~g}, 75 \%$ ). ### 3.4.5 The asymmetric synthesis of benzopyrans

The synthesis of (1R)-1-\{2-[(3-methylbut-2-en-1-yl) oxy] phenyl\}-3-phenylprop-2-yn-1-ol (206a)

Method 1: The same method was employed as described for the synthesis of the 187 a with the following quantities; $\mathrm{Zn}(\mathrm{OTf})_{2}(1.14 \mathrm{~g}, 2.9 \mathrm{mmol}, 1.1 \mathrm{eq})$ and $(+)-$ $(1 \mathrm{~S}, 2 \mathrm{R})$-N-methylephedrine $\quad(0.57 \mathrm{~g}, 3.16 \mathrm{mmol}, 1.2 \mathrm{eq})$ and purged with nitrogen for 15 minutes. Then, toluene ( 15 mL ) and triethylamine ( $0.64 \mathrm{~g}, 6.31$ mmol , and 2.4 eq ) were added by syringe. The resulting mixture was left to stir for 2 hours before the phenylacetylene ( $0.806 \mathrm{~g}, 7.9 \mathrm{mmol}, 3 \mathrm{eq}$ ) was added by syringe in one portion. After 15 minutes of stirring, 2- (3-methyl-but-2-enyloxy) benzaldehyde 197 ( $0.5 \mathrm{~g}, 2.63 \mathrm{mmol}, 1 \mathrm{eq}$ ) was added in one portion. After stirring for 7 days tlc monitoring showed new compound $R_{f}=0.5$ (hexane: diethyl ether, 70:30); purification by chromatography on silica gel, using 80:20 light petroleum spirit ( $60{ }^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether, gave the titled chiral secondary alcohol as a colourless oil ( $0.56 \mathrm{~g}, 72.73 \%$ ). ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ and IR and LRMS spectra are identical with the data for compound 198a. The following additional data was obtained. $[\alpha]_{D}=+10^{\circ}(c=1 \%$ ethanol), $95.0 \%$ ee HPLC (Chiralcel OD$\mathrm{H}, 10 \%$ i-PrOH-hexane, 254 nm ): $t_{R}=16.59$ major ( $97.55 \%$ ), $t_{\mathrm{R}}=12.06$ minor (2.45 \%).

HRMS (EI): [M-H] observed 291.1383 for $\mathrm{C}_{20} \mathrm{H}_{19} \mathrm{O}_{2}$ theoretical 291.1380,
Method 2: Propargyl alcohol 200a ( $1.0 \mathrm{~g}, 4.5 \mathrm{mmol}$ ) was placed in a 250 flamedry flask maintained under an atmosphere of nitrogen and at an ambient temperature and anhydrous DMF ( 20 mL ) was added. Potassium carbonate ( 2.5 $\mathrm{g}, 18.0 \mathrm{mmol}$ ) and potassium iodide ( $0.075 \mathrm{~g}, 0.45 \mathrm{mmol}$ ) were added followed by 4-bromo-2-methyl-2-butene ( $0.67 \mathrm{~g}, 4.5 \mathrm{mmol}$ ). The reaction mixture was left to stir for 3 hours after which tlc monitoring showed the presence of a new compound with an $\mathrm{R}_{\mathrm{f}}=0.49$ (petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ : diethyl ether $\left.60: 40\right)$. The colourless oil that was isolated was sufficiently pure. The yield was $(0.85 \mathrm{~g}$, $65.4 \%$ ). ee $\%=72 \%$

The synthesis of (1R)-1-\{2-[(3-methylbut-2-en-1-yl) oxy] phenyl\}-3- (4methylphenyl) prop-2-yn-1-ol (206b)

The same method was employed as described for the synthesis of the 187a with the following quantities; $\mathrm{Zn}(\mathrm{OTf})_{2}(2.3 \mathrm{~g}, 5.8 \mathrm{mmol}, 1.1 \mathrm{eq})$ and ( + )-( $1 \mathrm{~S}, 2 \mathrm{R}$ )- N methylephedrine ( $1.15 \mathrm{~g}, 6.4 \mathrm{mmol}, 1.2 \mathrm{eq}$ ) and purged with nitrogen for 15 minutes. Then, toluene ( 15 mL ) and triethylamine ( $1.3 \mathrm{~g}, 12.7 \mathrm{mmol}$, and 2.4 eq ) were added by syringe. The resulting mixture was left to stir for 2 hours before the 1 -ethynyl-4-methylbenzene ( $1.86 \mathrm{~g}, 16 \mathrm{mmol}$ ) was added by syringe in one portion. After 15 minutes of stirring, 2- (3-methyl-but-2-enyloxy) benzaldehyde 197 ( $1.0 \mathrm{~g}, 5.3 \mathrm{mmol}$, and 1eq) was added in one portion. After stirring for 7 days tlc monitoring showed new compound $\mathrm{R}_{\mathrm{f}}=0.6$ (hexane: diethyl ether, 70:30); purification by chromatography on silica gel, using 80:20 light petroleum spirit $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right.$ ): diethyl ether, gave the chiral secondary alcohol as a colourless oil ( $1.35 \mathrm{~g}, 83.85 \%$ ). ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ and IR and LRMS spectra are identical with the data for compound 198b. The following additional data was obtained. [ $\alpha]_{D}=-13^{\circ}$ ( $c=1 \%$, diethyl ether), ee\% $=96 \%$ HPLC (Chiralcel OD-H, 10\% $i$-PrOH-hexane, $254 \mathrm{~nm})$ : $\mathrm{t}_{\mathrm{R}}=7.9$ ( $98 \%$ ) major and $\mathrm{t}_{\mathrm{R}}=5.0(2 \%)$ minor HRMS (EI): [M-H] observed 305.1536 for $\mathrm{C}_{21} \mathrm{H}_{21} \mathrm{O}_{2}$ theoretical 305.1536.

The synthesis of (1R)-3- (4-methoxyphenyl)-1-\{2-[(3-methylbut-2-en-1-yl) oxy] phenyl\} prop-2-yn-1-ol (206c)

The same method was employed as described for the synthesis of the 187a with the following quantities; $\mathrm{Zn}(\mathrm{OTf})_{2}(3.42 \mathrm{~g}, 8.7 \mathrm{mmol}, 1.1 \mathrm{eq})$ and (+)-(1S,2R)N - methylephedrine ( $1.70 \mathrm{~g}, 9.5 \mathrm{mmol}, 1.2 \mathrm{eq}$ ) and purged with nitrogen for 15 minutes. Then, toluene ( 15 mL ) and triethylamine ( $1.92 \mathrm{~g}, 19.0 \mathrm{mmol}, 2.4 \mathrm{eq}$ ) were added by syringe. The resulting mixture was left to stir for 2 hours before the1-ethynyl-4-methoxybenzene ( $3.13 \mathrm{~g}, 23.7 \mathrm{mmol}, 3 \mathrm{eq}$ ) was added by syringe in one portion. After 15 minutes of stirring, 2- (3-methyl-but-2-enyloxy) benzaldehyde 197 ( $1.5 \mathrm{~g}, 7.9 \mathrm{mmol}, 1 \mathrm{eq}$ ) was added in one portion. After stirring for 7 days tlc monitoring showed new compound $\mathrm{R}_{\mathrm{f}}=0.48$ (petroleum ether ( 60 ${ }^{\circ} \mathrm{C}-80{ }^{\circ} \mathrm{C}$ ): diethyl ether, $70: 30$ ); purification by chromatography on silica gel, using $80: 20$ petroleum ether ( $60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}$ ): diethyl ether, gave the chiral secondary alcohol as a colourless oil $(2.35 \mathrm{~g}, 92.5 \%) .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ and $\mathbb{I R}$ and LRMS spectra are identical with the data for compound 198c. ### 3.4.6 Use of chiral pool and chiral auxiliary

The synthesis of (3R,5S)-5, 9-dimethyl-1-phenyldec-8-en-1-yn-3-ol (211a)

The same method was employed as described for the synthesis of the 187a, using the following quantities $\mathrm{Zn}(\mathrm{OTf})_{2}(2.64 \mathrm{~g}, 7.3 \mathrm{mmol})$ and (+)-(1S, 2R-Nmethylephedrine ( $1.45 \mathrm{~g}, 8.0 \mathrm{mmol}$ ) and purged with $\mathrm{N}_{2}$, stirred for 15 minutes whereupon toluene $(40 \mathrm{~mL})$ and triethylamine $\left(\mathrm{Et}_{3} \mathrm{~N}\right)(1.60 \mathrm{~g}, 15.9 \mathrm{mmol})$ was added via a syringe. after 2 hours phenylacetylene ( $2.0 \mathrm{~g}, 19.3 \mathrm{mmol}$ ) was added by syringe in one portion. After 15 minutes of stirring ( $R$ ) - ( + ) - citronellal ( $1.02 \mathrm{~g}, 6.60 \mathrm{mmol}$, and 1 eq ) was added in one portion. It took 10 days to complete the reaction and tlc monitoring showed less amount of the citronellal remained and revealed a new spot in $R_{f}=0.90$ (petroleum ether $\left(60^{\circ} \mathrm{C}-80^{\circ} \mathrm{C}\right)$ : diethyl ether, 70:30) to keep intact the diastereomers purification was not carried out. The yield of the title compound ( $1.5 \mathrm{~g}, 88.2 \%$ ) $[\alpha]_{D}=+110^{\circ}(\mathrm{c}=1 \%$, ethanol) ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\mathbf{~ \delta p p m : ~ 7 . 5 - 7 . 2 ~}(5 \mathrm{H}, \mathrm{m}, \mathrm{Ph}) ; 5.00(1 \mathrm{H}, \mathrm{t}$ brd, $\mathrm{J}=6.3$ $\mathrm{Hz}, \mathrm{CH}) ; 4.55(1 \mathrm{H}, \mathrm{t}, \mathrm{J}=5.5, \mathrm{CH}) ; 2.3(1 \mathrm{H}, \mathrm{s}, \mathrm{OH}) ; 2.0-1.75\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right) ; 1.75-$ $1.25\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right) ; 1.6\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right) ; 1.5\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{3}\right) ; 1.45-1.08(3 \mathrm{H}, \mathrm{m}, \mathrm{CH}$ and $\left.\mathrm{CH}_{2}\right) ; 0.92\left(3 \mathrm{H}, \mathrm{d}, J=6.5 \mathrm{~Hz}, \mathrm{CH}_{3}\right)$ major $=78 \%, 0.76\left(3 \mathrm{H}, \mathrm{d}, J=6.5 \mathrm{~Hz}, \mathrm{CH}_{3}\right)$ minor $=22 \%$.

The synthesis of (4S, 5R)-4-methyl-5-phenyl-3-propanoyl-1, 3-oxazolidin-2one (218a)

To a stirred solution of (4S,5R)-4-methyl-5-phenyl-1,3-oxazolidin-2-one ( 0.88 g , $5 \mathrm{mmol}, 1 \mathrm{eq})$ in dry THF ( 10 mL ) at $-78^{\circ} \mathrm{C}$ maintained under nitrogen atmosphere, was added $\mathrm{n}-\mathrm{BuLi}$, ( 2 mL of a 2.5 M solution in hexane, 5 mmol , 2eq). When the addition was complete the solution went from colourless to orange. The solution was left to stir for 30 minutes after which was added propionyl chloride ( $0.5 \mathrm{~g}, 5.5 \mathrm{mmol}, 1.1 \mathrm{eq}$ ). The mixture was left to stir at $-78^{\circ} \mathrm{C}$ for 30 minutes and then for 3 hours at $0{ }^{\circ} \mathrm{C}$. Tlc monitoring showed new compound with an $R_{f}=0.5$ (hexane: ethyl acetate $70: 30$ ). The reaction was quenched by addition of a saturated solution of $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ and the solvent was removed by rotary evaporation and replaced by ethyl acetate ( 20 mL ). The organic layer was extracted and consecutively washed with saturated a solution of sodium bicarbonate $(3 \times 20 \mathrm{~mL})$ and then brine $(3 \times 20 \mathrm{~mL})$. Finally the organic layer was isolated, dried over anhydrous magnesium sulphate, filtered and evaporated in vacuo. Purification by flash chromatography on silica gel (hexane: ethyl acetat, $70: 30$ ) gave the title compound as a colourless oil ( $1.15 \mathrm{~g}, 99 \%$ ). [a] $]_{\mathrm{D}}$ $=-40^{\circ}$ ( $c=2 \%$ methylen chloride); (lit. value is for the enantiomer to 218a: $+42, \mathrm{c}$ $\left.=2.1 \% \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)^{98-99}$
